I will confine this letter to the following fact. Within the last few weeks it has come to my knowledge that one of our oldest established and well-known West India merchants' house in London has, with a view to counteract the impending ruin caused by foreign Government sugar bounties, opened a house of business in New York, that a few months has satisfied them and their British West Indian friends that it is much more profitable to send their sugars to that foreign country than to the old country. The expend-

ment is so successful, that they are about opening branch houses at Philadelphia, Boston, and Halifax.

The last West Indian mail brought me a letter from an old friend of forty years standing, in which he remarks:—"I consider West Indians are in a much better position than in my recollection, now that we have regular communication with, and sales in, America."

It was only recently that the *Times*, in supporting its well-known free trade views, admitted that our exports were falling off; that our imports paid for in money were enormously increasing; that our foreign trade in exports was diminishing, except in machinery (machinery to make goods to meet us in every market); and that we should do well to cultivate closer intimacy with our own colonies.

I have reason to believe that half the exports from the West Indies this year will be sent to the United States, and I am of opinion that in a very few years these once magnificent possessions of the English Crown will have peacefully passed away from us, to the serious loss of our working classes; for they may depend upon it that those who receive the sugar will manufacture the machinery to make more, construct the carts to carry it, supply all the numerous requisites required in this costly manufacture, clothe the ladies, educate and Americanise their children. And I am able to state that already the loss to us at home is very considerable, caused by our ships being disused, and those sailing under the stars and stripes being alone used in carrying in each direction the industry of the two countries, while old England allows her ships to rot in dock, and her once industrious population to be left out in the cold.

Depend upon it there is too much energy and good sense left in us yet, for this state of things to continue much longer, and the cry from the working classes will be, Protection to native industry.

HENRY LOGGERS.

## NOTES ON BOOKS.

### Legendary History of the Maoris. New Zealand, 1880. Folio.

This paper consists of a series of extracts from a compilation of the "Legendary History of the Maoris" which has lately been presented to both Houses of the General Assembly of New Zealand, and printed. From the memorandum, by Mr. John White, it appears that the different canoes that came to these islands were distinct migrations of the same people, all coming originally from one distant home; having parted in the Pacific Ocean, they had rested for a time, some in one group and some in another of the different clusters of islands. "These various migrations; or parts of a great migration, had evidently met and become partially amalgamated with other branches of a race previously located in those islands. By this contact the Maori had learned words of another language, and had modified and altered his mythology, thereby giving rise to the difference apparent at the reunion of the Maori people in New Zealand." Mr. White found names in a genealogy of the Kings of Hawaiki, or Sandwich Islands, printed in 1838, which are identical with those of chiefs given in the genealogy of the New Zealand, Takitumu, and Arawa migration. In compiling this history of the Maoris, it is proposed "to give the oral traditions consecutively, placing those first which relate to actions most remote, giving, as far as practicable, in notes such of the parallel traditions which other Polynesians have preserved as may appear only relating to the same circumstances as those given in the Maori traditions, thus affording to those who may wish to continue the subject a starting-point for further research."

## THE LIBRARY.

The following works have been presented to the Library:—

*The Fields of Great Britain. A Text-book of culture.* By Hugh Clements. (London: Lookwood, and Co., 1881.) Presented by the Horticultural Buildings. By F. A. Fawks. B. T. Bateford.) Presented by the Author.  
*Catalogue of the Library of the Institute of* (London: Institute of Actuaries, Nov., 1880.) by the Institute.

*Aristology, or the Art of Dining.* By Thom M.A. With Preface and Notes by Felix (London: George Bell and Sons, 1881.) P. Sir Henry Cole, K.C.B.

*Chapters on the History of Old St. Paul* Sparrow Simpson, D.D., F.S.A. (London: Stock, 1881.) Presented by the Publisher.

## MEETINGS FOR THE ENSUING WEEK

MONDAY, JUNE 20TH. Domestic Economy Congress (Albert Hall, S.W.), 8 p.m. *Conversazione* Promenade.  
Asiatic, 22, Albemarle-street, W., 3 p.m.

TUESDAY, JUNE 21ST. Domestic Economy Congress OF THE SOCIETY OF ARTS, 11 a.m. *Readings and Discussions.*  
Statistical, Somerset-house-terrace, Strand, Mr. Hyde Clarke, "The English Station Regions of India, their Value and Importance Statistics of their Products and Trade." Zoological, 11, Hanover-square, W., 8 p.m.

WEDNESDAY, JUNE 22ND. Domestic Economy Congress (Royal Albert Hall), 11 a.m. *Evening Meeting of the Society of Arts*, 7 p.m.  
Geological, Burlington-house, W., 8 p.m.  
Towns, "Description of a New Species of the Middle Lias of Oxfordshire" 2. P. "Notes on the Occurrence of the Remains in the Lower Oligocene Strata of the Ham With a Note by Prof. H. O. Seeley. Hollingworth, "Description of a Peat-bed with the Boulder-drift at Oldham" Vine, "Silurian Unserial *Stomatopora* ones" 5. Mr. E. J. Dunn, "Notes on Fields, South Africa." 6. Mr. F. H. (New Comers from the Kelloway R. Sydney B. Buckman, "Descriptive Catalogues from the Sherborne District." Royal Society of Literature, 4, St. Martin 8 p.m. Mr. C. F. Keary, "The Genuine as in the Eddic Mythology." Part II. Sanitary Institute of Great Britain, 2, Con 8 p.m. Prof. W. H. Corfield, "The Sewage Question." Royal Botanic, Inner-circle, Regent's-park Evening Fête and Floral Exhibition.

THURSDAY, JUNE 23RD. Domestic Economy Congress (Royal Albert Hall), 11 a.m. *Reading Discussions.* 4 p.m. Lecture by Mrs. B. Antiquaries, Burlington-house, W., 8 p.m. Society for the Encouragement of Fine Art street, W., 8 p.m. Third *Conversazione*. Royal Society Club, Willis's-rooms, St. J. 8 p.m. Annual Meeting.

FRIDAY, JUNE 24TH. Domestic Economy Congress OF THE SOCIETY OF ARTS, 11 a.m. and 7 p.m. *Meeting.*

Royal United Service Institution, Whiteha Captain J. R. Lumley, "The Promotion the Prussian Service, their Training, and which their Efficiency and Capability as Tested."

Philological, University College, W.C., 8 Marshall, jun., "Aryan Roots, and the Semitic and Hamitic." Quaker Microscopical Club, University 8 p.m. Mr. B. W. Fries, "A New Spec from Honduras."

SATURDAY, JUNE 25TH. Domestic Economy Congress OF THE SOCIETY OF ARTS, 11 a.m. Physical, Science Schools, South Kensington. I. Mr. W. Grant, "Apparatus for Experiments on Current Induction." 2. Stewart and Mr. W. Stewart, "Experiments with a Modification of Daniell's Cell." Royal Botanic, Inner-circle, Regent's-park.

## ANNUAL GENERAL MEETING.

The Council hereby give notice that the One-HundredandTwenty-seventh Annual General Meeting, for the purpose of receiving the Council's Report and the Treasurer's statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new Members, will be held, in accordance with the

Bye-laws, on Wednesday, the 29th of J  
o'clock p.m.

The Council think it well to call the attention of Members to the above notice, and express their hope that Members may find it convenient to attend, and receive the report of the Council on the work of the Session.

(By Order of the Council)

H. TRUEMAN WOOD, Sec

## ART FURNITURE EXHIBITION.

The Exhibition of Works of Art Applied to Furniture, in connection with the Exhibition of the Arts at the Royal Albert Hall, is now open. A non-transferable season ticket will be sold to any member of the Society on application to the Secretary.

## PROCEEDINGS OF THE SOCIETY.

## DOMESTIC ECONOMY CONGRESS.

The Congress was opened on Monday evening, inst., with a *conversazione* and musical *soirée* in the Royal Albert Hall and Conservatory of the Royal Horticultural Society. There was a display of flowers in the Conservatory of the Royal Horticultural Society, which, with adjoining arcades, were illuminated by the various systems of electric lighting:—Siemens, by Messrs. Siemens; the Maxim incandescent light, by the Electric Light and Power Motor Company; and the Crompton light, by E. Crompton. An instrumental concert given by the band of the Royal Military Band, in the Royal Horticultural Society's Conservatory, and by the band of the Coldstream Guards, in the Royal Albert Hall. There was also a selection of vocal and instrumental music, by the scholars of the National Training School for Music, under the direction of Dr. Stainer; recitation of part-songs, by the students of St. John's Training College, conducted by Mr. Owen Jones, and by children taught on the Tonic Sol-fa method, conducted by Mr. John Evans, Inspector of Singing to the Board School of London. The exhibition of school needlework by children in public elementary and other schools at home and abroad, was on view in the East Gallery of the Royal Albert Hall.

The meetings for the reading of papers and discussion commenced with the meeting of Section Methods of Teaching and Examining in Domestic Economy, in the Great Room of the Society on Tuesday, June 21st, 1881, the PRESIDENTS OF ARLIE in the chair, with Sir RY COLE, K.C.B., as assessor.

The first paper read was by Lady Stuart Hogg, on "Teaching and Superintendence by Women in Elementary Schools."

Lady Stuart Hogg wished to add that, when abroad, she often noticed how very helpless our countrywomen

The husbands of the women, to whose ignorance domestic matters reference was made in the paper, were nearly getting far better wages than many mechanics always clerks in England, and yet they were unable to save any money, from having to maintain so many

servants. With regard to soldiers' wives, they were absolutely dependent on the ladies to cut out their things for them. She therefore thought that this movement would be of enormous value in making Englishwomen really as useful as the corresponding classes in both France and Germany.

The Rev. J. P. Fawcett, before reading the next paper, begged leave to state that he had recently heard that the inspectors of needlework in France were exclusively women.

Paper read was, "Suggested Outlines of a Plan for Establishing Women's Inspection of the Teaching of Domestic Economy by Counties," proposed by some members of the Executive Committee of the Congress (Sir Henry Cole, Rev. Newton Price, and Rev. J. P. Fawcett).

Mr. Mostyn Price (one of her Majesty's Inspectors of Schools for Monmouthshire) said all inspectors of schools would cordially agree with what had been said by Lady Stuart Hogg as to the desirability of inspection of needlework by ladies. He would, however, not wish to hamper them with so exhausting a work as a progress throughout the counties, and would suggest that some system should be organised rather for enabling the inspection to be carried out at headquarters. It might not be out of place altogether that, as a Government Inspector of Schools, he should offer a few remarks on the progress of teaching domestic economy in his district for the criticism of ladies present. Being a Government officer, acting under the direction of the Education Department, he must not be supposed for a moment to be officially criticising any part of the syllabus of the Code sanctioned by his superiors. And any remarks he might make, therefore, must be taken simply as offered in his private character of listener at this Congress. Mr. Price then gave an account of the need, in his Monmouthshire district, for such instruction as was proposed in the papers read, and of the work being done there.

Paper on "County Organisations for Teaching Branches of Domestic Economy," was read by the Rev. Newton Price, M.A.

Mr. Stephen Mitchell said that the method of teaching by books was at fault. Papers were sent in to the Science and Art Department in great numbers, but, though without any outward distinctions, they could be traced to particular schools by internal evidence, from containing the same mistakes and the same kind of blunders, showing that the children did not know what they were writing about, but that they were simply copying from text-books, without any knowledge of method or principle. He, therefore, deprecated the use of books for the children, though they would be useful for teachers; and the children should be shown how they could do things for themselves. With regard to the remark that while some ladies were able to work successfully, others rashly following them only exposed themselves to ridicule, that result simply arose from the ladies not knowing what they were teaching.

Mr. Kempton said it was very satisfactory that girls were being taught domestic economy in the schools, and with good results, but he also thought boys should be taught social and political economy as kindred subjects.

Mrs. Gover advocated the claims of factory girls to instruction of this kind. Thousands of them would as readily attend classes for their benefit as they would go to penny readings. Evening classes might usefully be established, as the Factory Acts compelled a cessation of labour at eight o'clock.

Miss Kenrick thought a divided inspectorship would not be so satisfactory as the present system. It was a mistake to suppose every woman knew something about sewing; and some who undertook that important branch of instruction were anything but competent to do so.

The instruction of very young children should be left to women; but it was a very different thing to say that they should be entrusted with all examinations, though ladies might properly be appointed to assist the inspectors in the examination of needlework, and such matters with which a man could not be so well acquainted. Confusion only would result from the appointment of two sets of inspectors, and an over amount of work would be extracted from the children. Cookery was not a subject which could be examined on, or made a means of obtaining a Government grant, but should rather be taught so as to be brought into the children's homes. Principles should be instilled into their minds by the help of experiments; and the girls' homes would then benefit by their teaching. Half the battle would be won, when once the children's minds were interested.

Sir Henry Cole agreed that very young children were better taught by women than by men. The two formidable words, "domestic economy," simply meant "home life," the knowledge of which should be inculcated (as it did, in fact, begin from the earliest age at home) before reading, writing, and arithmetic were taught; cleanliness was not a matter for text-books or physiological diagrams.

Miss Guthrie Wright said this Congress had particularly to do with the subject of teaching domestic economy in public elementary schools. Such instruction was as necessary for the higher as for the working classes, and if good examples were shown by the upper and middle classes, the subject would be much more popular and acceptable to the working classes, than if pushed among the latter exclusively. At the school in Edinburgh, the object arrived at was to teach subjects which could be made useful at home. That, of course, presented a very wide field for future work, and included sanitary teaching alike for rich and poor. The recognition of elementary teaching in the Code was only a matter of time; but in private schools considerable attention had been given to it, and the managers had been induced to take it up. Public attention in this direction was much required. More than was really possible to teach, in the shape of languages, drawing, and music, was expected from girls before leaving school, and it would be well if domestic economy were made, to a considerable extent, a substitute. Three subjects might be practically taught, cookery, laundry work, and cutting out clothes. A great deal of good had been done by the public cookery classes for older persons, and homely teaching could also be given at mothers' meetings, care being taken to leave out all technical expressions on the scientific part of the question.

Dr. Mann said that this Congress would be specially valuable if it should succeed in bringing before the public the great necessity for women doing women's work. He did not think ladies had ever before taken so much practical interest in these matters as they were doing now, and hoped this was but the first of a series of meetings which would show they could work for that object.

Miss Fanny Calder said that it had been found in the North of England that cookery could not be taught theoretically, and they had been considering how they could best teach and examine upon it practically. Grants for practical work of that description had been applied for, and Mr. Mundella promised to give the matter full consideration. Where the teaching had been theoretical it had been unsatisfactory. The inspectors had recommended that some plans should be devised for the adoption of new practical methods, in connection with South Kensington.

Paper read by Dr Mann, on "Domestic Economy, Defined and Arranged for Elementary School Teaching."

Mrs. Fenwick (member of Yorkshire Ladies' Gym-

of Education, and hon. sec. York County Cookery) advocated the appointment of lady inspectors for schools in domestic economy subjects, as, had had a classical education could not be expected to acquire the necessary knowledge of cookery and work. Influence should, therefore, be brought on the Government to appoint properly qualified inspectors.

Miss Phillips referred to the reluctance of girls to attend classes, and urged that girls should not be deterred by too many subjects being brought before them.

Mr. Chadwick was an advocate for women's work, and said the best work was in schools which had female teachers. A great deal would be made by substituting for the idle children's wranglers, that of ladies who were accustomed to the work of their own families.

A paper was read by Miss Andrews, on "The of Domestic Economy in the bringing up of Children."

Mr. Chadwick remarked, on the question of that on visiting a pauper school he had found a pig being fed on the waste from the tables. Panacea Workhouses there were cooking and washing apparatus established, and everything been systematized, with the result that 90 of the children now got good situations one-third formerly.

The meeting then adjourned for luncheon.

On the re-assembling of the meeting, Mrs. B. the chair.

Mrs. Barnett read Mrs. Greenup's paper, "Teaching of Domestic Economy in Schools."

Sir Henry Cole said it was more pedantry that people could go through the world with virtues, if they knew nothing about how to them. It was fallacious to hold, according to that until children had passed the fourth star were not to be taught cleanliness, thrift, and He inquired of Lady Stanley of Alderney was not of opinion that children three years not be taught something of domestic economy they knew anything of reading, writing, and arithmetic.

Lady Stanley of Alderney thought it would teaching sewing and needlework at such a considered children would be much better rubbing their fingers in perfect liberty. For age was quite early enough for children to go

Miss E. M. Brant (Board School, Great Back Herts) read a paper on "Method of Teaching Economy."

Sir Henry Cole thought that if young people through such instructions as was advocated paper, girls taking domestic situations would prepared to fill them than at present.

Mrs. Ross (manager of a London Room having spoken in favour of such instruction,

Mr. Alsager Hay Hill deprecated mere teaching, and suggested the promulgation of suggestions in the cheap popular newspaper periodicals.

The Rev. E. F. M. McCarthy's paper, "Education and Inspection in relation to Domestic Economy" was read by the Rev. J. F. Fawcett.

Mrs. Lewland Williams read a paper on "and Domestic Economy." (Second Session.)

Mr. Fawcett protested against whole denunciation of theoretical and the exclusive of practical teaching. The mistress leading the

not necessarily know anything of cookery, qualifications should be demanded of the they were required of the children.

read a paper on "Teachers' Certificates"

Mr. Martin read a paper on "Domestic Schools and Training Colleges."

J. Harrison's (F.G.S.) prize paper, "The Art of Teaching Domestic Economy in Primary Schools," was read.

He disliked class legislation, that would make the poor the acquirement of knowledge by needlework, and general domestic education was not demanded of the rich. At compulsory education imposed was obligatory

He urged that the teaching in these subjects both practical and theoretical, and adapted according to age, and not by order to reach dull girls.

He differed from Miss Becker's views on

and the Rev. J. P. Faunthorpe added a few remarks, and the meeting terminated.

On the evening of Wednesday, 22nd June, was held at the Royal Albert Hall, at 11 a.m., the annual meeting of the N.C.E.R. in the chair, and the Rev. E. J. as assessor.

#### SECTION B.—NEEDLEWORK.

Miss Cole read a paper on "Needlework Certificates."

Mr. de Witt's paper, on "The State of the Primary Schools of France," was read.

He spoke specially in reference to needlework in Birmingham Board Schools, and pointed out the importance of teaching the art of cutting out.

She had found children in the first seven years of age, able to knit stockings. Materials in work might be used with in other ways a great deal might be done with children's work "pretty" for them. One of the objects was having a number of cheap dolls for children of standards 4, 5, and 6, and that it would be a temptation to girls to do work if one of the dolls was given in prize for the best work. To possess a doll, she believed, would work steadily for a year.

He recommended that boys in infant schools should be taught to use the needle, and learn to sew and knit the girls. Little boys got very tired of sewing, and the only resource was to give them lessons to do over again. She had found boys as young as 2½ years to knit, making them to learn that they might sit up to bed, as they would have to do if they do something to occupy their fingers.

Mr. Price was requested by Lady Airlie to show her in her employment was able to do the stockings for his family. He quite admired the ability of boys being taught generally

He gave an instance of a school in Devon where boys were so instructed with advantage.

Mr. Price said that in the Duchesse of Leeds' school were given for such work; and, on the other hand, done by the boys was superior to that of the girls.

Lady Stuart Hogg called attention to a remark by M. Le Gouvello, a great authority on educational matters in France, on the apparent inability of peasant men to find any occupation in the evenings beyond idly smoking; and the utility of giving them a means of employing their leisure in needlework of some kind.

Mrs. Dacre Craven remarked that in the Franco-German war, the Germans in hospital were able to occupy themselves usefully with the needle, while the French had great difficulty in passing the long hours. It would be well if boys in English schools were taught to sew and knit as in the German schools.

Rev. Newton Price said that one result of this Congress would be a recommendation to the authorities of the Educational Department in favour of the instruction of boys in these matters.

Miss Sempill's paper on "Simultaneous Teaching of Needlework" was read.

Rev. Newton Price gave an instance, on the authority of a lady present, of an old soldier having made, of his own design, from silk cuttings, a very fine patchwork quilt, which afterwards received the approval of the Duchess of Edinburgh.

Miss Cole's paper, "Notes on Clothing and Dress," was read by Miss Stanley.

Miss Kenrick suggested that the children should be put through examinations as to the amount and quality of the materials required to be made up into garments, and said that interspersing the lessons with questions for that purpose would enliven the dullness of the work. It was very desirable that children should be taught to combine colours tastefully, and so avoid the discordant results of ill-selected and badly arranged finery. Boys she could not admit to be quite so clever with the needle as they had been represented, but still much might be done in teaching them.

Miss Stanley offered a few remarks on the inculcation of ideas of suitability in dress to height, figure, and occupation. Students should be carefully instructed in those matters, and teachers should avoid appearing unnecessarily ornamented in their work.

Mrs. Floyer urged the necessity of a good example being set in matters of dress by teachers to the children in their charge.

Paper by Madame Van Eyck-Hardamann, read by Miss Mallett, "The Teaching of Plain Needlework in the Netherlands."

A Lady objected to so much time as six hours being given in the last standard to instructing girls who might be urgently wanted at home, and thought four hours would be sufficient.

Rev. Fredk. Lawrence (secretary to the Church of England Mourning Reform Association) offered a few remarks on the objects of that body, for which he asked support, and said that one of its objects was the abolition of crape for ladies as a sign of mourning.

Mrs. Erskine's paper, "Notes on Teaching of Needlework in Elementary Schools," was read by Miss Stanley.

Miss Curry's Paper, "How I Teach Sewing," was read by Miss Webb, and the meeting adjourned.

On the re-assembling of the meeting, a lecture was given by Mrs. Floyer, Demonstrator in Plain Needlework to the London Institute for the Advancement of Plain Needlework.

Mrs. Floyer said, with regard to the simultaneous teaching of needlework, as reading, writing, and arithmetic had for many years been taught in that way, it had occurred to her that the same method might advantageously be used in respect to needlework. The

question was, how was it to be done, and the first thing necessary was the adoption of a simple plan for avoidance of waste, and to render tools unnecessary as far as possible, the teacher always having the whole class at command. With the object of simplification, the method of hemming, for instance, had been reduced to six movements, and instead of being allowed to move their fingers in any way they pleased, they were instructed in position drill for their hands. This kind of instruction at once rendered children constructing, and not merely consuming, members of society. Specimens of work done after short periods of teaching were then referred to and explained. On the next subject of knitting much needless difficulty had been occasioned in teaching children, and they could be easily taught to do for themselves what was often done for them by teachers, in the shape of "casting on" and in other ways. Explanation was then given on the blackboard of a system for demonstrating proper modes of taking stitches, thus giving the children definite standards to work by. The great bugbear of teaching was how to teach classes of sixty or seventy children the way to cut out, in the absence of materials for them all. It had, therefore, been thought advisable to utilise the kinder-garten principle of using chequered slates, and it was found that the children had no difficulty in extending their work from the patterns after every three lessons. A great difficulty was to keep children clean who came from the poorest homes, and, in view of that fact, the cleanly appearance of the work shown was very creditable to the teachers. The importance of drill among children was really hardly understood. Teachers should recognise the necessity of self-drill in the first place, and its results would show themselves in the condition of their schools. Boys should be taught needlework as a means of giving them greater facility in the use of their fingers—a much needed requirement for them—for it was a common and true saying that "their fingers were all thumbs." Old copy-books might be used for making patterns. More specimens were then referred to, and the work analysed as showing the efficacy of the simultaneous plan of teaching. The most earnest application by the children was often stultified by the failure of their teachers to supply them with proper standards.

Paper read by the Hon. Albertine Grosvenor, on the "Watford and West Herts Association for the Improvement of Elementary Needlework in Schools."

Rev. Newton Price said formerly there was a great want of faith in the power of the inspectors' power of judging needlework, and teachers had candidly admitted that, until the association came into existence, needlework was very much neglected by them, knowing the inability of the inspectors to understand it, in favour of other subjects which would do them more credit, but since the efforts of the association had been pointed in this direction, the great progress made had astonished the managers.

Miss Phillips read a paper on "Needlework."

A Lady remarked that a great deal had been said about what was being done for the women of the future, and said she would be glad to hear what was being done for the grown-up women of the present.

Miss Allen read her prize paper, "Instruction in Needlework."

The evening meeting on Wednesday, 22nd June, was held at seven o'clock, at the House of the Society of Arts, when the chair was taken by Mrs. MANN, Sir H. COLE acting as assessor.

#### SECTION A.—FOOD: ITS COMPOSITION AND ITS VALUE, ITS FUNCTIONS.

A paper, by Miss Buncle (Dumbarton), on "Teach Practical Cooking," was read by Miss

Sir Henry Cole said this lady had received eight prizes awarded by the Society for a paper teaching of cookery.

The Rev. Nugent Price said a circular had been to her Majesty's inspectors with regard to the instruction given in cookery and domestic economy matter having been very slightly dealt with in the book. When the results had been analysed and it was intended to lay them before the Education Department. Cookery was now taught in 300 including all the large towns except Manchester inspectors themselves seemed very favourable teaching of this subject, but he was sorry to see some ladies would prefer that children should draw or philosophy. He hoped that eventually it would be made to keep down the expense of cookery, and no attempt be made to turn over to rich men's establishments. He was proud he was the first to introduce this subject into elementary school.

Sir Henry Cole said some years ago they had Government Inspector to visit the School of Cookery he was much shocked at finding the children taught to clean pots and pans. This gentleman author of the phrase "Culinary Treatment," of cooking, but he hoped it would soon give proper term.

Miss Harriet Martin next read a paper "Points Considered in Teaching the Second Domestic Economy," explaining in detail the system of instruction followed in Whitelands College.

Sir Henry Cole thought the teaching of cookery was carried out more perfectly at Whitelands than elsewhere.

Dr. Mann wished to draw attention to the fact that this paper referred especially to the duties of teachers. For many years he had been acquainted with this college, and it was quite marvellous what results were obtained there in a course of two years.

Dr. Frances Hoggan said, in listening to the diaphanous mentioned, she had been sorry to see that table dishes, especially as many of the teachers going to neighbourhoods where there would be a large amount of vegetable food at command. It was possible to obtain everything requisite to build up and repair waste from the vegetable kingdom and it was, therefore, of great importance that a branch of cooking should receive due attention. 2,500 vegetarian dinners were now given in London, and there was great difficulty in getting cooks competent in this branch. It would be desirable, therefore, that where a class could be formed, a teacher of vegetarian cookery should be specially engaged. She was a great admirer of simplicity in everything, and preferred nitrogenous and non-nitrogenous foods in plain distinctions of flesh-forming and heat-producing recent researches had shown could not always be obtained.

Miss Martin admitted that it was an omission to have mentioned the cooking of vegetables, but simply for the want of space. All the girls taught how to boil a potato. She preferred the combustible or non-combustible, or oxidisable or non-oxidisable, as physiological terms, to chemical.

Miss Barnett imagined that what was required was something more than the proper use of a potato. She had frequently been asked for a recipe for producing a variety of vegetarian dishes, and in them.

paper on "A Method of Teaching Cookery," by Miss Mayley, was next read.

Mrs. Cole said this subject of culinary treatment bore him in public documents for some years, but was only two places where female teachers could teach cooking, and the department did not even then teachers should have a knowledge of cooking.

R. Barnett next read a paper on "Cookery and Teachers."

Cole said there were several points of great interest in this paper. It was very important that a teacher of cookery should be well educated, but he knew how that was to be secured.

He suggested that a common kitchen as well as a school should be placed at the top of model lodging houses. It would be a great benefit if the rich would see that the liquor in which poultry or meat was given to the poor, instead of being thrown into the sewers.

Mrs. Mann next read a paper on "The Economical Instruction and Management of School Kitchens."

Her paper on "Domestic Cookery, as Taught to the pupils of a Voluntary School," by Mrs. Ebenham, was read.

Miss S. Cole then read a paper on "The Philosophy of Cookery."

Catharine Wright wished to remark that all connected with schools would agree with Mrs. Mann's view that cookery should be taught practically, and, she, she believed it was taught in that way. In Edinburgh, they had not a special kitchen, but endeavoured to make the conditions as nearly as possible parallel to those which obtained in their own homes. Strict attention was paid to the use of material, the object being not to make cooks, but to improve the cooking in the homes of the poor. There was much attention to the lessons connected with twelve demonstrations, and were given to girls who were old, and to those who had passed the fifth class. Boys were also allowed to attend in some cases.

The teaching of Cookery in Training Colleges was very great importance. It was very important to women of good education for teachers of cookery: not see how anyone else could teach it properly.

Mrs. Cole said a book might be bought for 1s. which would show how to teach a child of four years of age the rudiments of cooking, which he would recommend the attention of the meeting. He explained the details which could be very easily conveyed to a child's mind, and the practical operations in which they might take part. The title of the book was "Cookery of Home Life." He had to state on the part of a Diocesan Inspector that £5 was quite a small expenditure for utensils if some sort of cookery were at hand. He believed cookery teaching failed from attempting too much.

The next paper was on "The Importance of Teaching the Great Benefits to be derived from the Use of Whole-meal Bread," by Miss Yates.

Mr. Fawcett thought the whole subject of domestic science should be taught, not cookery alone. In Edinburgh they endeavoured to teach the whole subjects and with it except washing, to which they had not attended. She suggested that the whole subject should be considered necessary to the training of teachers, as the whole was connected together. She pointed out the manner in which cookery was taught in schools which were employed.

W. S. Mitchell read a paper on "The Food Sanitation at Bethnal-green," and the advantages to be derived from a study of it.

A few remarks from Mr. Clements, the Conference, followed until Thursday morning at eleven o'clock.

## MISCELLANEOUS.

### GAS FOR LIGHT AND HEATING.

On Tuesday, June 14, Dr. C. W. Siemens, F.R.S., read a paper before the conference of gas managers held at Birmingham, on "Gas Supply, both for Heating and Illuminating Purposes." When, within the memory of living men, the gas-burner took the place of the oil-lamp, the improvement was so great that the ultimate condition of perfection appeared to have been reached. It is only in recent years that much attention has been bestowed upon the utilization of by-products with a view of cheapening cost, and that the consumer has become alive to the importance of having a gas of high illuminating power, free from noxious constituents, such as bisulphide of carbon, thus providing a stimulant for progress on the part of the gas-works manager. This condition of things has been rudely shaken by the introduction of the electric light, which, owing to its greater brilliancy and cheapness, threatens to do for gas what gas did for oil half a century before. The lighting of the City of London and of public halls and works furnishes proof that the electric light is not an imaginary, but a real competitor with gas as an illuminant; and it is indeed time for gas engineers and managers to look seriously to their position with regard to this new rival. For my own part (Dr. Siemens said), I present myself before you both as a rival and a friend—as a rival, because I am one of the promoters of electric illumination; and as a friend, because I have advocated the use of gas for heating purposes during the last 20 years, and am not disposed to relinquish my advocacy of gas both as an illuminating and as a heating agent. Speaking as a gas engineer, I should be disposed to regard the electric light as an incentive to fresh exertion, confidently anticipating achievements by the use of gas which would probably have been long postponed under the continued regime of a monopoly. Already we observe, thanks chiefly to Mr. Sugg, both in our thoroughfares and in our apartments, gas-burners producing a brighter light than was to be seen previously; and although gas will have to yield to the electric light the illumination of our lighthouses, halls, and great thoroughfares, it will be in a position, I believe, to hold its own as a domestic illuminant, owing to its convenience of usage, and to the facility with which it can be subdivided and regulated. The loss which it is likely to sustain in large applications as an illuminant would be more than compensated by its use as a heating agent, to which the attention of both the producer and the consumer has latterly been largely directed. Having, in the development of the regenerative gas furnace, had opportunities of recognising the many advantages of gaseous over solid fuel, I ventured, as early as 1863, to propose to the Town Council of Birmingham the establishment of works for the distribution of heating gas throughout the town, and it has occurred to me to take this opportunity (when the gas managers of Great Britain hold their annual meeting at the very place of my early proposal) to lay before them the ideas that then guided me, and to suggest a plan of operation for its realization which, at the present day, will not, I hope, be regarded by them as Utopian. The proposal of 1863 consisted in the establishment of separate mains for the distribution of heating gas to be produced in vertical retorts, that might be shortly described as Appold's coke ovens, heated by means of "producer" gas and "regenerators." The Corporation applied for an Act of Parliament, but did not succeed in obtaining it, owing to the opposition of the gas companies, who pledged themselves to carry out such an

undertaking, if found feasible by them. I am ready to admit that at the time the success of the undertaking would have involved considerable difficulties; but I feel confident that the modified plan which it is my present object to bring before you would reduce these difficulties to a minimum, and would open out a new field for the enterprise of those interested in gas-works. The gas-retort would be the same as at present, and the only change I would advocate in the benches is the use of the regenerative gas-furnace. This was first successfully introduced by me at the Paris Gas-works in 1863, and has since found favour with the managers of gas works abroad, and in this country. The advantages that have been proved in favour of this mode of heating are—economy of fuel; greater durability of retorts, owing to the more perfect distribution of heat; the introduction of an additional retort in each bed, in the position previously occupied by the fire-grate; and, above all, a more rapid distillation of the coal, resulting in changes of four hours each, whereas six hours are necessary under the ordinary mode of firing. The additional suggestion I have now to make, consists in providing over each bench of retorts two collecting pipes, the one being set aside for illuminating and the other for a separate service of heating gas. I shall be able to prove to you, from unimpeachable evidence, that the gas coming from a retort varies very greatly in its character during progressive periods of the charge; that during the first quarter of an hour after closing the retort the gas given off consists principally of marsh gas ( $\text{CH}_4$ ) and other gases and vapours, which are of little or no use for illuminating purposes; from the end of the first quarter of an hour, for a period of two hours, rich hydro-carbons, such as acetylene ( $\text{C}_2\text{H}_2$ ) and olefiant gas ( $\text{C}_2\text{H}_4$ ) are given off; whereas the gases passing away after this consist for the most part again of marsh gas, possessing low illuminating power. According to the figures given in the experiment of M. Ellissem, President of the French Society of Gas Engineers, it appears that nearly two-thirds of the total production of gas takes place in the above period, while the remaining third is distilled during the first quarter of an hour and the last hour and three-quarters. It hence follows that by changing the direction of the flow of gas at the periods indicated, allowing the first results of distillation to flow into the heating gas main, then for two consecutive hours into the illuminating gas main, and for the remainder of the period again into the heating-gas main, one-third volume of heating and two-thirds of illuminating gas would be obtained, with this important difference, that the illuminating gas would be of 16.16 instead of 13.5 candle power, and that the heating gas, although possessed of an illuminating power of only 11.05 candles, would be preferable to the mixed gas for heating purposes in being less liable in its combustion to deposit soot upon heat-absorbing surfaces, and in giving, weight for weight, a calorific power superior to olefiant gas. The working out of this plan would involve the mechanical operation of changing the direction of the gas coming from each bench of retorts at the proper periods of the charge. In order to distribute the two gases a double set of gas mains would certainly be required, but these exist already in the principal thoroughfares of many of our great towns, and it would not, I think, be difficult to utilise them for the separate supply of illuminating and heating gas, the latter being only taken into the houses and establishments where it is asked for by the occupiers. The public could well afford to pay an increased price for a gas of greatly increased illuminating power, and the increase of revenue thus produced would enable gas companies to supply heating gas at a proportionately reduced rate. The question may be asked whether a demand would be likely to arise for heating gas similar in amount to that for illuminating gas; and I am of opinion that, although the present amount of gas supplied for illuminating purposes ex-

ceeds that for heating, the diminution in price latter would very soon indeed reverse these proportions. Already gas is used in rapidly increasing quantities in kitcheners, for the working of gas-engines, fire-grates. As regards the latter application here mention that an arrangement for using coals jointly in an open fireplace combined with contrivance for effecting the combustion of the heated air, has found favour with many of the grate builders and with the public. As regards use of illuminating gas, I have one more to make, which I feel confident will be by you with interest. The illuminating effect in a gas flame depends partly upon the carbon developed in the solid condition in the flame, and partly upon the temperature of these particles are heated in the act of combustion. Having shown how by separation a gas of luminosity may be supplied, it remains to be seen the temperature of combustion may be raised may be effected by certain mechanical arrangements whereby a portion of the waste heat produced by the flame itself is rendered available to heat the air sustaining the combustion of the flame—say Fahrenheit, or even beyond this point. The arrangement I have adopted for this purpose is a burner of the ordinary Argand type, mounted in a small chamber of sheet copper, connected with a pipe of copper, projecting upwards through the burner, and terminating in a cup-like extension a point about four inches above the gas orifice level with the top of the flame. A small mass of copper fills the cup, projecting upwards from it in a rounded pointed form. The copper vessel surrounding it is contracted at its upper extremity with a directing a current of air against the gas-jet burner, and on its circumference it is perforated for admission of atmospheric air. The bottom is formed of a perforated disc covered with wire and wire gauze also surrounds the circumference of the perforated cylinder. The external air is heated by passing through these “regenerative” surfaces, the flame is thus fed with air, heated to the point indicated, which, by more elaborate arrangements might be raised to a still higher degree. The fire-clay in the centre of the burner, which is of redness, serves the useful purpose of completing the combustion of the gas, and thus diminishes the blackening of the ceiling. The arrangement of transferring the heat from the tip of the flame supporting its combustion was applicable to an open bat’s-wing burner, but I have not yet been able to ascertain accurately the amount of increase of light that may be realised with this class of burner. From a purely theoretical point of view, it can be seen that of the calorific energy developed in the coal gas a proportion (probably not exceeding 1 per cent) is really utilised in the production of luminous light; that even in the electric light nine-tenths of the light set up in the arc is dispersed in the form of heat, and only one-tenth only is utilised in the form of luminous light. These calculations, but it is important to call attention to them in order to show the large margin for us for practical improvements. I may here mention that another solution of the problem of the incoming air by the waste heat of the gas combustion has lately been brought under notice by my brother, Frederick Siemens, who has essentially from the plan I have suggested, as he draws the flame downwards through a glass apparatus, and thence into a chimney. In both these methods of intensifying a gas flame probably find independent application, under different circumstances. By the combined employment of these processes for separating the illuminating gas from the gas with the arrangement for intensifying the

gas flame, the total luminous effect produced by the consumption of coal gas may, according to the gas given, be increased threefold, thus showing that deleterious effects now appertaining to gas illumination are not inseparable from its use. My principal object in preparing this communication has been to call attention generally to the important question of improved gas illumination, and more particularly to the subject of a separate supply for heating gas, which, tried into effect, would lead, I am convinced, to social results, the importance of which, both to gas companies and to the public, it would be difficult to estimate.

## E CULTIVATION OF LAND IN KAZEROON (WESTERN PERSIA).

Land in Kazeroon is private property. If the cultivation be undertaken by the landowner himself, he provides seed for an acre of one "gao" of cultivation (the "gao" representing the extent cultivable by one ox), viz., 1,000 lbs. of wheat and 1,000 lbs. of barley, and pay about 14 krans (the kran being equal to 100 lbs.) for the labour of ploughing and sowing. He takes in kind 11 per cent. of the yield of his harvest to himself, and 20 per cent. to the reapers, who have to undertake all the duties appertaining to the collection of the harvest and the carriage into the stores of the landlord. The landowner also pays 2 to 4 per cent. for threshing or treading the corn. Other than a landowner undertaking a cultivation has to pay to the landlord 9 per cent. in kind from the out-turn of his land as rent for one "gao" of land, and 14 per cent. to the Government as tax; his other expenses are the same as those incurred by a landowner. Consul-General Ross states that the agriculturists of Kazeroon are of two classes, viz., the "ryot-i-padiashah" and the "ryot," the former being always looked down upon as the lower class, and subjected by Government to more oppression than the others. The ryot cultivator thus only pays more taxes to Government, but has to pay his taxes in cash instead of in kind, and at 30 per cent. above market value. He is also obliged to provide a certain quantity of straw to Government for the use of the army whenever required. A ryot, when a landowner, and cultivating his own grounds, has to pay 10 per cent. on his harvest in cash, and at the above rate of valuation. A poor ryot pays about 60 krans annually in cash to Government; and there is another class of ryots who are obliged to buy at 30 per cent. above market value, a certain portion of the produce received by Government as taxes. A wealthy ryot is entirely at the mercy of the authorities, a sum of about 1,000 krans being annually levied from him. The rent of one "gao" of land is from 100 to 600 krans, according to the locality. To commence cultivation, an outlay of about 15 tomanins (the tomain being equivalent to 3d.) is necessary, and is distributed as follows:—for one ox, 50 krans; seed, 60 krans; labour, about 14 krans; straw and cotton seeds, 16 krans; and sundries, 15 krans. It is also necessary for a ryot when undertaking four or more "gaos" of cultivation, to maintain at least one donkey. The quantity of grain required for cultivating one "gao" of ground is about 2,000 lbs. In the case of "saifee" or summer cultivation, no distinction is made by Government between a ryot and a landowner; "saifee" sowings are always undertaken by the proprietors of water and agriculturists conjointly, the proprietor providing the water and ground, and the agriculturist finding the seed, labour, implements, &c. Should the landowner, however, not be a landowner as well, any other landowner would be but too glad to permit his land to be used for "saifee" cultivation gratis, inasmuch as the soil becomes enriched by manuring, which "saifee" cultivation necessitates. The time taken for "saifee" sowing is about seven months, the follow-

ing being cultivated—tobacco, water melon, marsh melon, vegetables, cotton, sesame seeds, lentils, rice, gram, &c. A tax of 20 per cent., *ad valorem*, on the out-turn, is levied by Government, three-fifths of which is payable by the proprietor of the water, and two-fifths by the cultivator, and the balance is equally divided between the proprietor and the cultivator. Rice and grain, however, form an exception, and are cultivated under the following conditions:—The agriculturist recoups himself for the quantity of seed supplied by him after harvest. He then has equal shares with the water owner, who alone pays Government taxes as follows:—If a ryot, he pays three-fifths of his share to Government; if a non-ryot, he pays only half, the agriculturist paying no tax on his share. In all cases it is thoroughly understood that the Government share of the produce is to be carried to Government store at the cultivator's expense. The approximate value of the produce on the spot is for wheat, from 40 to 60 cents. per maund (the maund being equivalent to 3 lbs. avoirdupois); barley, from 25 to 30; gram, from 50 to 80; sesame, from 70 to 100; maithee, from 15 to 20; dhall, from 15 to 20; cotton, from 2½ to 3 krans; and rice, from 50 to 80 cents. The annual expenses of a ryot cultivator in Kazeroon, with a wife and two children, are 10 tomanins per annum. The yield of wheat and barley is from ten fold to twelve fold in a good year, and three fold to four fold in a bad one; rice, in a bad year, yields twenty fold, and in a very good year, sixty fold; cotton, five fold in a bad year, and ten fold in a good year. Irrigation is generally conducted by means of kanats, and the water in all cases is allowed free passage across grounds, even though not belonging to the proprietor of the kanat; should the proprietor of a kanat not wish to undertake any "saifee" cultivation, he could still be made liable by Government to such taxes as may be due by the cultivator; no taxes whatever are levied on gardens in Kazeroon. In the cultivation of the poppy, which is largely grown, the proprietor provides the land, seed, and the expenses of sowing, the cultivation is then made over to the ryot, who undertakes all the labour necessary for the tending of the crop till the season of cultivation, when the proprietor pays for the labour of incision, about one kran per man per day; the out-turn is then equally divided between the landowner and the ryots. The cultivation of opium is also untaxed. A good deal of water is wasted in Persia owing to the long distances it has very often to travel before reaching a land eligible for its security against raids, &c., and to damages constantly sustained by watercourses, which, owing to the social conditions of the country, it is very often beyond the reach of the ryot to travel out of the jurisdiction of his village to repair. There are also large tracts of fertile land which remain waste owing to their proximity to the main roads, as no village having cultivators on such spots can possibly prosper or enjoy the least immunity from the exacting demands of Government officials, and the thefts and robberies committed by the "Tiyat" tribes on their passage along the country thoroughfares.

## NOTES ON BOOKS.

Melbourne International Exhibition, 1881. The Official Catalogue of the Exhibits, with the Introductory Notices of the Countries Exhibiting. Melbourne, 1880. 2 vols., 8vo.

This is a second edition of the catalogue, and contains a complete record of the exhibits. The general classification adopted consisted of 82 classes in ten groups:—

Group 1. Works of art; 2. Education and instruction, apparatus and process of the liberal arts; 3. Furniture and accessories; 4. Textile fabrics, clothing and accessories; 5. Raw and manufactured products; 6. Machinery, apparatus and processes used in the mechanical industries; 7. Alimentary products; 8. Agriculture; 9. Horticulture; 10. Mining industries, machinery and products. Prefixed to the list of exhibits of each Court is a statistical account of the country which sent them.

## GENERAL NOTES.

**National Training School of Music.**—A series of students' concerts is now being given in the arena of the Albert Hall. Future concerts will be on the afternoons of Wednesday, June 28, Friday, July 8, Wednesdays, July 8, and 20, commencing at 4 p.m. The public will be admitted to these concerts on payment of 1s., but students will be supplied with tickets for their friends gratis.

**Ecclesiastical Art Exhibition at Newcastle.**—An Exhibition of Ecclesiastical Art will be held at Newcastle-on-Tyne during the meeting of the Church Congress from October 3 to 8. The Exhibition will include articles of every description used in the building and adornment of churches, or in connection with the services thereof—stone and wood carving, stained glass, brass and metal work, gold and silver plate, bells, embroidery, tapestry, organs and harmoniums, church chairs, mosaics, &c., a large gallery being set apart for the display of cartoons, designs, pictures, architectural drawings, &c. It has been decided to admit also all kinds of school appliances, books, &c., useful in the furtherance of education. There will be also an extensive loan collection of pictures, photographs, designs (old and new), embroidery, carvings, and objects of ecclesiastical art generally. Applications for space, or permission to exhibit, should be addressed to Mr. J. Hart, manager, Ecclesiastical Art Exhibition, 88, Southampton-street, Strand, London, W.C.; or Mr. G. J. Baguley, 45, Carlisle-street, Newcastle.

**Gold in the United States.**—According to a report of the Director of the United States Mint lately issued, the total gold circulation of the United States, including bullion in the Treasury, amounted, at the commencement of May, to 520,000,000 dollars, of which about 284,000,000 dollars was held as Treasury and national bank reserves, and 236,000,000 dollars was in actual circulation. There has been a total gain of gold coin and bullion to the country since July, 1879, of 234,000,000 dollars, of which 85,000,000 dollars was added to the Treasury, 59,000,000 dollars to the banks, and 140,000,000 dollars to the active circulation. The total amount of gold in the country makes a fair showing compared with the principal countries of Europe, being exceeded by only two. The amount estimated to be in England in 1880 was 598,000,000 dollars, of which 428,000,000 dollars was in actual circulation; and France, with 827,000,000 dollars of gold, had a circulation of about 816,000,000 dollars. The larger proportion of gold in active circulation in the latter two countries the director attributes in part to the fact that their coinage consists most exclusively of denominations of less value than 5 dollars. The largest English gold coin is the sovereign, equivalent to 4-86½ dollars of American money, while in France, out of a total coinage during the last 77 years of 1,743,288,000 dollars of gold, nearly 89 per cent. was in pieces of less than 5 dollars.

**Oyster Culture in Tasmania.**—A successful attempt to breed oysters in a bed specially prepared for their reception appears to have been made in Tasmania, at a place bearing the appropriate name of Little Oyster Cove, where a number of these bivalves were placed towards the end of last year, in the expectation that they would "spat" or spawn in the month corresponding to the month of July, which is the

breeding season of the European oyster. It was, till the middle of February that the usual "heavy fall of spat" were observed, the water to be full of the minute oysters just extruded from their shells. In March an examination was made which had been placed to collect the young they were found to be thickly covered with it. If any reasonable proportion of these mollusks matured, there is every prospect of the oyster culture being carried out in a most successful manner in Tasmania. The total number of young oysters in Little Oyster Cove is variously estimated to have been from 2,500,000,000 to 40,000,000,000 per cent. come to maturity and market four years hence. An enterprising Colonist who conducted the experiment to reap a rich reward.—*Colonies and India.*

## MEETINGS FOR THE ENSUING WEEK.

**MONDAY, JUNE 27TH.**—Anglers' Association (at the Society of Arts), 8½ p.m. Conference on Water Fisheries Act.

Royal Institution, Albemarle-street, W., 5 p.m. Monthly Meeting.

Royal Geographical Society, University of London, 8½ p.m. Lieut.-Colonel. "The Country of the Tekke Turkmans and Murghab Rivers."

Public Analysts, Burlington-house, Piccadilly. Special General Meeting to Consider the Report of Mr. A. Wynter Blyth, "The Estimation of Wines and Tinctures, &c." and "Patterns which drop of various Fats under certain conditions." 2. Mr W. F. K. St. John of Wynter Blyth's Apparatus for the Estimation of Ether as applied to Milk Analysis, and for Griffin's Gas Muffle Furnace." 3. "Some remarks on the Swedish Laws as to Arsenic really Prohibited."

**TUESDAY, JUNE 28TH.**—National Health Society (at the Society of Arts), 7½ p.m. Mr. S. "The Science and Art of Sanitary Plumbing." "House Drainage and Ventilation."

Statistical Society, Somerset-house-terrace, Strand. Annual Meeting.

Anthropological Institute, 4, Grosvenor-street, 8½ p.m. Right Hon. Sir H. Bartle Frere. Laws Affecting the Relations between Savage Life, as Bearing upon the Death with Aborigines."

Royal Horticultural, South Kensington, 8 p.m.

**WEDNESDAY, JUNE 29TH.**—SOCIETY OF ARTS. Adelphi, W.C., 4 p.m. Annual General Meeting.

**THURSDAY, JUNE 30TH.**—Victoria Institute (at the Society of Arts), 8 p.m. Annual Meeting by the Right Hon. the Lord O'Neill.

Society for the Encouragement of Fine Arts, 1, Pall Mall, W. Morning Meeting.

**FRIDAY, JULY 1ST.**—National Health Society (at the Society of Arts), 7½ p.m. Mr. S. "The Science and Art of Sanitary Plumbing." "Lecture IV."

Royal United Service Institution, Whitehall, 8 p.m. Major J. C. Arlidge, "The American Artillery." Geological Association, University College, 8 p.m.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,493. VOL. XXIX.

FRIDAY, JULY 1, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## PROCEEDINGS OF THE SOCIETY.

## ANNUAL GENERAL MEETING.

Annual General Meeting, for receiving the report from the Council, and the Treasurers' Statement of Receipts, Payment, and Expenditure for the past year, and also for the Election of Officers, was held, in accordance with the Bye-laws, on Wednesday last, the 29th of June, at 8 o'clock, P. J. BRAMWELL, F.R.S., Chairman of the Council, in the chair.

The SECRETARY read the notice convening the meeting, and the minutes of the previous annual meeting.

Following candidates were proposed, balloted, and duly elected members of the Society:—

Percy Leonard, 8, Arboretum-street, Derby, Engineer's Office, Northern Division, Midland Railway, Derby.

David, M.P., 25, Pont-street, S.W.  
William James, Farnley-house, Chelsea,

Edmund Bowen, 51, Courtfield-gardens, South Kensington, S.W.

John, Maple Durham, Oxon.

James Barnes, 77, Old-road, Middleton, near Manchester, and Jessamine-house, Barton-on-Irwell, Lancashire.

Robert Charles, 10, Henry-street, Carlisle.

Frederic Wilson, 14, Augusta-road, Ramsgate.

George Bernard, M.D., 3, Chesterfield-street, W.

Horatio, St. Lawrence, Putney-hill, S.W.

C. F., City Surveyor's office, Manchester.

William, Caterham.

St. Worcester.

William Alfred Harry, Coombs Croft-house, Warrington.

W.B., Keythorpe-hall, Leicester.

Henry Somerson, 1, The Elms, St. Ann's-road, Warrington, S.W.

G. W., Eathwaite-lodge, Hawkehead, near Warrington.

G., 24, Bull's Head Exchange-chambers, Manchester.

William, Stoneleigh, Sale, Cheshire.

Edwards Albert, 97, Finsbury-pavement, E.C.

Carlo, 116, Piccadilly, W.

Samuel, 11, Queen Victoria-street, E.C.

Everard, Dartford, Kent.

Matthias Thomas, 77, Chancery-lane, W.C.

Johnson, Thomas Hilton, F.C.S., 36, Rawcliffe-road, Rice-lane, Walton, Liverpool.

Johnston, Thomas Ruddiman, F.R.G.S., 108, George-street, Edinburgh.

Jones, Charles, 35, Great Queen-street, Lincoln's-inn-fields, W.C.

Kennard, Stephen P., J.P., 17, Kensington-palace-gardens, W.

Lasseter, Frederic, 5, Porchester-gate, Hyde-park, W.

Lloyd, Alfred, B.A., Bush-lane, Cannon-street, E.C.

Nosotti, Charles, 395, Oxford-street, W.

Olsen, Ole Theodor, F.R.A.S., 40, Cleethorpe-road, Grimsby.

Owen, Lancaster, 38, Gloucester-gardens, W., and Engineers' Office, G.W.R., Paddington, W.

Paul, Joseph John Dawson, Eaton, Norwich.

Pfeil, A. L. A., Frognaal, Hampstead, N.W.

Phillips, Alfred, 23, Cockspur-street, S.W.

Rutson, Albert, 7, Half-moon-street, Piccadilly, W.

Saunders, H. A. C., 11, Old Broad-street, E.C.

Stevenson, George Ernest, The Gas Works, Peterborough.

Thomas, Sidney Gilchrist, F.C.S., 27, Tedworth-square, Chelsea, S.W.

Tweddell, Ralph Hart, 14, Delahay-street, Westminster, S.W.

Tweedie, George R., F.C.S., 24, Josephine-avenue, Brixton-rise, S.W.

Walker, Philip F., 29, Prince's-gate, S.W.

Wickham, William Henry, 14, Essex-street, Strand, W.C., and Wimbledon-hill, Surrey.

Williamson, William Blizard, Providence Works, Worcester.

Young, Charles Edward Baring, 12, Hyde-park-terrace, W.

The CHAIRMAN nominated Dr. Mann and Capt. C. F. Gardner scrutineers, and declared the ballot open.

The SECRETARY then read the following—

## REPORT OF THE COUNCIL.

The Council have now to lay before the members their report for the One Hundred and Twenty-seventh Session of the Society, and, in doing so, they are happy to be able to repeat the congratulations which their predecessors in office have now for some years past been justified in offering to the general body of members. The Society is, they are glad to think, flourishing in every way; its numbers are increasing, now for the first time for some few years, its finances are in a sound condition, its usefulness is as great as ever, and the Council are well assured its influence is as widespread and its reputation as high as at any period of its long and prosperous career.

## I.—ORDINARY MEETINGS.

Looking back through the list of papers read at the ordinary meetings of the past Session, it is satisfactory to be able to state that neither in popular interest nor in intrinsic value, do they compare unfavourably with those read in any former Session.

It has been the aim of the Council always to give the members the earliest possible opportunity of hearing, from the lips of the discoverers themselves, or of other competent persons, accounts of the various applications of science to purposes of daily life, of which our time is so productive. It is not now-a-days possible, or even desirable, for a Society to compete with the public newspapers as

For the next meeting, fortunately, the aid of Professor Graham Bell, who happened to have come to England on a short visit, was secured. Professor Bell readily acceded to the invitation of the Council, that he should bring the Photophone, his latest and one of his most wonderful discoveries, before the Society, in the same manner as, four years ago, he had introduced his earlier invention, the Telephone. His paper was listened to by a crowded meeting, and the inadequacy of the accommodation

At the last meeting before Christmas, Edwards, the Secretary to the Deputy-Ministry of the Trinity House, read a very able paper on "Life by Means of Sound." The meeting of the paper was read had the advantage of being presided over by Dr. Tyndall, and nearly all the principal authorities on this subject attended and took part in the discussion. Mr. Edwards gave an interesting account of the measures which have been taken by the Trinity House for the improvement of the harbor.

and signals, to the safety of our coasts. subject was dealt with in March by Thomson, who brought before the system he has for some time been of enabling each lighthouse to identify sailing ship by means of a special signal. have rise to a long and valuable discussion indeed may be said to have done towards the clearing up of a difficult and aged question.

Christmas recess, Professor Fleeming Stodred, to a London audience, assuring the proper sanitary condition which he has for some time successfully at Edinburgh. Professor Fleeming Stodred led to the formation of an association the Edinburgh Sanitary Protection and the Council understand that this, one or two others of a similar description, is going favourably.

Mr. Stodred's paper on "Success and Failure in Gold Mining" gave a good account of the system usually adopted for the extraction of the ore; and also quoted the author's views on the system and process which were the great severity of the winter about as such as to render Mr. Lock's audience very small one, and hardly more successful at an adjourned meeting for the reading of the paper. The paper, however, of much interest, the subject being one of which the members are aware, was then and attracted a great deal of attention. Mr. Stodred's paper on "Trade Prospects" consisted of several dealing with social and economic, rather than with scientific matters. That many of our members are interested in this character, and it is thought that the advantages result from the opportunity for the discussion of such subjects. This class may be enumerated Mr. Sedley Stodred on "The Participation of Labour in the Enterprise;" Professor Bonamy Smith on "Buying and Selling;" and Mr. Thomson's paper upon the "Trade Marks and Acts." The first and principal Act passed at work for five years, and the period within which it is possible to register a new trade mark has therefore expired. This good opportunity for Mr. Johnson to state the results of the working of the Act, and to point out various improvements which, in addition to that of other authorities, seem desirable. There was also a paper upon "The Art of the Glass Worker," by Mr. Cornelius Walford, who has made results of careful research into the subject for a long time back. The relations of Art to industry have always been one of the most important departments of the Society's work. Nor has it been neglected in the selection of papers for reading at the meetings. Under this head are to be mentioned Mr. Hungerford Pollen's paper on "The Art of the Pottery Worker," read in February; Professor Stodred on "The Artistic Use of Precious Metals," read a little later in the Session; and, at the close of the Session, the paper by Mr. Stodred, of the Whitfriars Glass Works, on "The Manufacture of Glass for Decorative

The papers yet remaining to be noticed include one on "River Conservancy," by Mr. Cresswell, a subject of which he has treated before in the Society's Room, and one which has for some years attracted special notice from the Society. Next came a paper by Mr. Edward Whympster, giving an account of the writer's ascents of Chimborazo and Cotopaxi last year. In this case, as in that of Professor Ball, it was found absolutely necessary to restrict the admissions, but in order to give the greatest possible number of members the opportunity of hearing Mr. Whympster, the loan of the lecture theatre at South Kensington was obtained for the evening, through the kind permission of the Lords of the Committee of Council on Education.

## II.—INDIAN SECTION.

The Indian Section has had a most successful Session this year, all the papers being of a high character, and some of them extremely important. The work of the Section began with a communication from Sir Richard Temple, on "Forest Conservancy in India." This is a subject with which Sir Richard Temple has been closely connected, and the paper which he read upon it was both interesting and important. Had it not been that the meeting took place during the week of the severe snow-storm, which, for a time, almost suspended traffic in London, the audience would, doubtless, have been larger than it was, but, even under these unfavourable circumstances, the reading of the paper was well attended. Mr. Hyde Clarke's paper on the "Indian Gold Fields," read at the next meeting of the Section, formed a valuable and indeed a necessary supplement to the paper previously read by Mr. A. G. Lock, on a similar subject, at one of the ordinary meetings of the Society. Mr. Lock, of course, had dealt with the question of gold mining generally, while Mr. Hyde Clark treated the special subject of the "Gold Fields of India." The third paper was an admirable exposition of "The Results of British Rule in India," by Mr. J. M. Maclean, who is recognised as an eminent authority on the subject. Sir George Campbell followed with a subject with which his name has long been connected—"The Tenure and Cultivation of Land in India." The fifth paper was by General MacLagan on the "Building Arts of India," while the sixth and concluding one was by General Sir Arthur Phayre, on "British Burma." This paper is really a model of complete information in a concise form. It has been suggested at different times that it would be useful if a selection were made from the papers which have been read at the various meetings of the Indian Section since its formation, with a view to its separate publication. The Council do not feel themselves able at present to offer any opinion on this matter, but they propose to take it into further consideration.

## III.—FOREIGN AND COLONIAL SECTION.

In the Foreign and Colonial Section the business of the Session commenced by a paper on "The Industrial Resources of South Africa," by Sir Bartle Frere, G.C.B., who opened the section seven years ago with an inaugural address. This paper was notable for the large amount of valuable information supplied regarding the

progress and prospects of a district to which recent events have so strongly drawn public attention. Mr. Cust also contributed an interesting sketch of the classification and structural relations of the languages of Africa, in the discussion of which Dr. Koelle, the distinguished philologist, took a prominent part. An account of the present state of the diamond fields of South Africa, and the progress of their operations, was communicated by Mr. E. W. Murray, who had been connected for ten years with the district. Mr. Happle Hall's memoir of the colony and dominion of Canada was most suggestive and practical, containing as it did an admirable historical sketch of the commercial progress of this important dependency. Mr. Westgarth's remarks on the trade relations that connect her colonies with Great Britain, excited a considerable amount of attention, and led to a lively discussion. The immediate interest of Mr. Gubbins' paper upon Loo Choo, and its curious two-fold connection with the Empires of China and Japan, was materially increased by the presidency of Sir Harry Parkes, K.C.B., her Majesty's Minister at the Court of Japan, and by his promise of a future contribution to the Section concerning the commerce of the country with which he is officially connected.

#### IV.—SECTION OF APPLIED CHEMISTRY AND PHYSICS.

Five papers were read in this Section; a sixth had been set down upon the list, but the sudden and severe indisposition of the author of it, Mr. Shelford Bidwell, prevented its being read. In the first paper, Mr. James Mactear gave an account of his system of manufacturing sulphate of soda. It will be in the recollection of the members that, three years ago, Mr. Mactear described to the Society the furnace known by his name, at a meeting of the Chemical Section, in a paper for which the Council awarded a medal at that time. In his second paper, Mr. Mactear described the various improvements which he has since made in his furnace, with the object of rendering its action continuous. The second paper read in the Section was by Mr. J. Y. Buchanan. Mr. Buchanan is well known as having occupied the position of chemist to the *Challenger* expedition, and the experience he then gained enabled him to write a very valuable paper upon "Deep Sea Investigation, and the Apparatus Used in it." The paper may be said to be fairly exhaustive of its subject, and, it may be hoped, will take rank as a monograph upon it. This was followed by a paper by Professor Perry, on "The Future Development of Electrical Appliances." The subject of Professor Perry's paper may be said to be the application of electricity to purposes other than illumination. The same remark applies to it as has been applied to papers on electrical subjects read before the ordinary meetings of the Society—that it attracted much attention from the members, and brought together large audiences. Mr. Stillingfleet Johnson dealt with a subject which has frequently of late been before the Society in his paper on the effects of impure water upon health; while Professor Huntington concluded the business of this Section by an able résumé of recent progress in the manufacture and application of steel.

#### V.—CANTOR LECTURES.

It has been the practice of recent years for three sets of Cantor lectures in each session consisting of some five or six lectures each, is hardly necessary to say that most of them with which the Cantor lectures deal are it would be difficult to deal with them or even in much longer courses; but, on the other hand, it is often inconvenient for member arrangements to attend week by week extending over a period of six weeks. Session just passed, therefore, arrangements were made for a greater number of courses, courses themselves were made up of a number of lectures. There were accorded series of Cantor lectures. Of these, the delivered by Professor Church, his subject "The Scientific and Artistic Aspects of and Porcelain." These lectures were during the early part of the Session, to Christmas, and were well attended. course after Christmas was by Mr. Rigg, the subject being "Watchmaking course also attracted good audiences; on former occasions, when the subject of of lectures was connected with any London a limited number of admissions were; watchmakers and their apprentices, many availed themselves of the opportunity of a their knowledge of the theory of their business. Rigg's lectures were specially valuable for want of technical literature in this country subject of watchmaking; and this fact will their value when they make, as they show their appearance in the *Journal*. The large audiences at the Cantor lectures of the Session, were those which attended the third course "Scientific Principles Involved in Electric Lighting" by Professor Adams. For these it was crowded to its utmost capacity. Prof. lectures were amply illustrated by a fine set of apparatus, and also by examples of several principal systems of electric lighting. Of systems, the Brookie lamp, Siemens (or Berrin) lamp were shown at work, other is "candles" being exhibited, but not lights interest also attached to the exhibition Swan of his new incandescent light. next course was by Mr. Alan S. Cole, on "Art of Lace-making." These lectures were illustrated by some valuable specimens of lace for the purpose, and also by a fine collection of transparencies, representing the various patterns of lace, which were shown on the aid of a lantern. The Cantor lectures Session were concluded by an important lecture "Colour Blindness," delivered by Mr. E. D. Carter. Mr. Carter drew special attention to effect of colour blindness upon various trades and brought before his audience the test have recently been devised for the detection of this curious defect. The Council think to say that Mr. Carter, being a member of the Society, could not accept the usual fee for his lecture.

#### VI.—JUVENILE LECTURES.

In these lectures, the Council have also endeavoured to consider rather than the usual interesting and instructive to the young.

man to strictly confine the range of the subjects properly coming within the Society. They, therefore, invited Mr. Osmann, the well-known naturalist, to give a short course of lectures at Christmas, a subject which he has made his own, the sense and instinct of animals. The lectures were well attended, and appeared to afford satisfaction to the audience that listened to

#### VII.—ALBERT MEDAL.

The Council feel convinced that the award of the Albert Medal, this year, to Dr. A. W. Hofmann, "for the eminent services rendered to the arts by his investigations in organic chemistry, and for his successful labours in promoting the cultivation of chemical education in England," will give universal satisfaction. For the past forty years, Dr. Hofmann, one of the earliest and most distinguished pupils, endowed with an indefatigable zeal, equalled the success of those labours, in the development of some of the most important branches of chemistry. While the very high scientific value of Dr. Hofmann's researches has been, from time, recognised in this country by the award to him of the Royal and Copley Medals of the Royal Society, and of the Faraday Medal of the Chemical Society, the fact that some of his remarkable researches laid the foundation of the dye and tar colour industry, while others furnished important contributions to its rapid development, has been recognised by the award of the Albert Medal by the Society of Arts.

There are, however, other quite separate and not less prominent claims to this distinction which the Society of Arts desire to recognise in awarding the medal to Dr. Hofmann. When the Royal College of Chemistry was established, in 1845, by the late Prince Consort as its first Professor, the Society of Arts, for the acquisition of chemical knowledge, was in this country one of a very limited number, and within the reach of but few; and the requisite for the pursuit of chemistry as a profession, and for its application to the arts and the Arts, had to be sought in Germany and France. It is due to the indefatigable energy and perseverance of Dr. Hofmann, in the most formidable difficulties—to his remarkable success as a teacher and lecturer, and to the peculiarly his own, of inculcating his rich and enthusiastic love of chemical research—that the Royal College of Chemistry has become developed into a world-renowned centre of chemical science; while its success has given a great impetus to the cultivation of that science and of its application to the Arts and Industries of the United Kingdom. Among English chemists who have, in later years, so largely contributed to the development of the chemical industries and to the advancement of chemical knowledge, some of the most prominent are those to whom the Society of Arts now award its highest distinction.

#### VIII.—MEDALS.

According to the usual custom, the Council

have awarded Silver Medals for certain of the papers read during the Session before the Society, at the ordinary meetings and in the different Sections. For the present year, eight medals have been awarded; of these, three were given for papers read at the ordinary meetings, two for papers in the Indian Section, one for a paper in the African Section, and two for papers in the Chemical and Physical Section. The Council also passed a vote of thanks to one of their own members, Mr. Preece, for the very interesting paper which he read, upon "Recent Advances in Electric Lighting." The following is a complete list of the awards:—

- To Professor ALEXANDER GRAHAM BELL, for his paper on "The Photophone."
- To E. PRICE EDWARDS, for his paper on "Signalling by Means of Sound."
- To ALEXANDER SIEMENS, for his paper on "The Electrical Railway, and the Transmission of Power by Electricity."
- To Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., D.C.L., for his paper on "Forest Conservancy in India."
- To J. M. MACLEMAN, for his paper on the "Results of British Rule in India."
- To Sir HENRY BARTLE EDWARD FAIRER, Bart., G.C.B., G.C.S.I., D.C.L., LL.D., for his paper on "The Industrial Products of South Africa."
- To J. Y. BUCHANAN, F.R.S.E., F.C.S., for his paper on "Deep Sea Investigation, and the Apparatus used in it."
- To Professor JOHN PREECE, for his paper on "The Future Development of Electrical Appliances."

#### IX.—EXAMINATIONS.

Those who have interested themselves in this department of the Society's work, are aware that considerable changes were made in the examinations, after due announcement, a year ago, many of the subjects in which examinations had been held being struck off the list. The reasons which induced the Council to take this step have been fully stated in the *Journal*, and in previous annual reports. The past year was the first under which the new system came into practice. According to the plan adopted, only those subjects were retained in which it did not appear that any other examination was provided for students, the subjects retained being Clothing, Cooking, Health, Housekeeping, Political Economy, and Music. In all these subjects, except in Music, there has been a serious falling off, the numbers of candidates for the present and for last year being as follows:—

	1880.	1881.
Clothing .....	84	3
Cookery .....	118	98
Health .....	114	43
Housekeeping .....	50	14
Political Economy .....	40	27
Music .....	324	321

The cause of this diminution is doubtless to be found in the fact that the abandonment of the greater number of subjects has reacted on those retained, for many candidates who took up some of the latter as supplementary, do not now enter at all. In former examinations a separate day was given for each of the Domestic Economy subjects; there is now only one day for the whole number.

The Council are much indebted to the Examiners

and Art Department for the assistance which they have rendered, in permitting candidates for the Society of Arts Examinations to be examined in connection with the candidates at the Government Examinations.

#### X.—PRINCE CONSORT'S PRIZE.

The Prince Consort's Prize of Twenty-five Guineas, originally offered by his Royal Highness the late President of the Society, and graciously continued by her Majesty the Queen, was offered annually to the candidate who, obtained under certain conditions, and within a space of four years, the greatest number of First-classes in the subjects for examination. The altered scope of the examinations rendered it necessary for the Council to ascertain her Majesty's wishes in respect of the prize, and she gave it as her opinion, that as the system of education, which the Prince Consort had desired to encourage, was now to a large extent carried on by the Science and Art Department, the time had arrived when the award of the prize might well be discontinued. No offer of the prize was therefore made for the past year.

#### XI.—EXAMINATIONS IN PRACTICAL MUSIC.

In consequence of the success of these examinations, which were held for the first time in 1879, it was thought desirable that there should be two examinations in London during the year, instead of only one, and it was determined that they should take place in January and in July. For the January examination, 75 candidates entered, 72 presenting themselves for examination, some of whom were examined in singing as well as in playing. 42 certificates of the first-class were awarded, and 33 of the second. 59 of these candidates were students of the pianoforte, 4 of the organ, and 2 of the violin; and there were 23 vocalists. 4 candidates entered for honours, of whom 2 took first-class certificates and 1 a second-class. It is worth noticing that 2 of the candidates for the general examination were awarded full marks by the examiners. Dr. Hullah, the Society's examiner, expresses in his report a very favourable opinion upon the results of these practical examinations as a continuation of the theoretical examinations in the theory of music started by the Society of Arts in 1869. Dr. Hullah also remarks that in the period of twenty years during which these examinations have been held, there has been "an amount of progress in execution, style, ear, reading, and general musical culture, no parallel to which, in the same space of time, has been presented in any other age or country." A practical examination in music has also been held at Glasgow under the supervision of the Society.

The second examination for the current year will be held at the Society's House during the week commencing Monday, the 4th July. For this a larger number of candidates have entered than at any previous examination.

#### XII.—MUSICAL EDUCATION COMMITTEE.

This committee, which was appointed the year before last, and whose first report was referred to in the last annual report of the Council, have been continuing their labours. They have issued two short reports dealing with the system under which music is now taught in elementary schools, and also

with the proposals at present under consideration for the establishment of a college of music in connection with the Training School for Music at Kensington. The first of these reports, a second report actually published by the Society, has appeared in the *Society of Arts Journal*. The committee's third report can be obtained on application at the Society's office.

#### XIII.—NATIONAL TRAINING SCHOOL

In November last, a statement was made to H.R.H. the Duke of Edinburgh, as President of the Committee of Management of the National Training School for Music, reminding the founders of the school of the period of five years, for which the school was originally established, would expire at the end of 1881. This statement held out the hope of a permanent school of music, under the management and control of the State (as originally desired by the Society of Arts), might, at no remote date, be established; but it also stated that the conditions which the committee of management of the school were carrying on, were still in progress, and that however favourably they terminated, it would not be possible to introduce such a new institution by Easter last. The committee, therefore, appealed to the founders that they should renew the scholarships for the period from Easter 1881 to Easter 1882. The appeal was addressed to the Society as having four scholarships at the school. The matter was fully considered by the Council, and it was determined that a sum of £160, the amount of the annual amount granted by the Government for the establishment of its four scholarships, be placed at the disposal of the National Training School for Music towards the maintenance of the school. In making this grant, the Council directed the committee of the school to decide in what manner the money should be employed in founding fresh scholarships, continuing, or in any other way which might seem to the committee.

The two scholarships provided by subscription from members of the Society and others renewed for one year, one of the subscribers, W. Atkinson, having very liberally increased the amount he formerly gave, in order to make the full sum of £80 should be forthcoming.

The grant of £160 made by the Society, stated, has been used by the committee of management of the school to endow four scholarships which have been awarded as follows:—Bénard, pianist; F. W. Crooke, violinist; Synner, pianist; and Florence M. pianist.

The two scholarships subscribed for by members of the Society and others have been awarded to Miss pianist, and Alice Menzies, pianist.

The actual result of the appeal of the founders was the endowment of 82 scholarships, and the committee have also received a grant for general purposes, amounting to £1,000 besides the £160 grant from the Society. The committee have disposed of, as above, in founding scholarships. Dr. Sullivan, retired from the Principalship, Dr. Sullivan, late Vice-Principal, has been appointed, and Dr. Sullivan has been placed as a member of the Committee of Management of the school.

school has been recently examined by a of examiners appointed by H.R.H. the of Wales, and consisting of Sir Michael, Sir Julius Benedict, Sir George Elvey, Dr. Hullah, Otto Goldschmidt, Esq., W. S. s, Esq., and Henry Leslie, Esq. The report gentlemen, after dealing fully with details, ades as follows:—(The examiners) "consider the school has done and is doing much good. It would be a national misfortune if it did continue its operations. The examiners hope those occupying the leading position in its ion will spare no efforts to secure that great ratum, a Musical and Dramatic Conserva- n, which shall be the central home for all is most talented and artistic in Great Britain dependencies." is satisfactory to be able to state, that twenty- of the scholars left the school last Easter, to : upon the active duties of the profession for h they had been preparing themselves at the l. Most of these, it is reported, have ob- id good positions, some as public singers or ers, some as organists and choirmasters, and as teachers.

#### XIV.—PATENT-LAW.

the address delivered by Mr. Bramwell, as man of the Council, at the opening of the on, special attention was drawn to the subject he improvement of the Patent-law. The il have had under consideration the best the Society of Arts could take in order to : about the much-needed improvements in the and they came to the conclusion that the most plan to pursue would be to draft a Bill, which l be, so far as the powers of those engaged it could make it, a perfect measure, whether ; it might be possible eventually to pass all its ions into law. The Council appointed a com- to prepare this Bill. The Committee has met ntly and has given much thought and atten- to the subject. The Council would have been f it had been possible to have presented their Bill to the members before the conclusion of sion ; but the work, as might be expected, l too great for this to be done, and, though tman is now engaged upon the Bill, under structions of the committee, it has not been possible to get it so far advanced as to t it before the present time. So soon as the of the committee and the Council is fairly ste, the Council propose to bring their before a meeting of the Society, specially oned to consider it. After it has been fully sed by such a meeting, it will then be recon- d by the Council and their committee, and res will be taken to get it introduced into ouse of Commons for the next Parliamentary n. The Council think it wiser to defer, until can bring the whole matter forward in a lete shape, any statement as to the principal ions which are being introduced into the they can only say that the committee has a careful attention to all the suggestions h have been made by various bodies for mprovement of the law, and that they to produce a measure which will, so far t is possible, give satisfaction to those ent to form an opinion upon it. The

Council consider this to be one of the most im- portant pieces of work which they have undertaken for some time, and they think that if, before the next Session of Parliament begins, they can bring forward a thoroughly good and practical measure for the reform of the Patent-laws, that the year in which this has been effected will not have been a barren one, so far as the Council's labours are concerned.

#### XV.—ART FURNITURE EXHIBITION.

It may be remembered, that some years ago, a series of Art-Workmanship Exhibitions was held by the Society of Arts. The movement commenced in 1862, towards the end of which year an applica- tion was made by the Society of Wood-carvers, asking the Society of Arts to assist them in holding an Exhibition of Wood-carving. The application was agreed to ; the Society of Arts made a grant of £30 and a silver medal, the Wood-carvers' Society promising £15. The Exhibition was held in the latter part of the Session of 1863, and prizes were awarded in three classes for wood-carving. In the following year, it was determined to extend the scope of the Exhibition, and prizes were offered to workmen in ten different classes. For the competition seventy works were submitted, and prizes were awarded in nearly all the classes. For the following year — 1864 — the Council offered prizes amounting to upwards of £500. The works were arranged in two divisions—1. Works to be executed from prescribed designs ; and, 2. Works to be executed without prescribed designs. In the first division there were 18 classes. Thesecond division comprised three classes of wood- carving. In response to this offer, 87 works were sent in, and prizes to the extent of £274 were awarded among 37 competitors. The Exhibition of these works was held at Christmas, 1864. Previous to holding the next year's competition, a meeting of workmen was held, the scale was extended, and the amount of prizes increased to £600. As before, the works were arranged in two divisions, according as they were executed from designs or without designs. The classes in the first division were identical with those of the previous year, a class being added, however, for illumina- tions. The competition in 1866 does not seem to have differed materially from those of former years. From this year, up to 1871, the competitions were continued in much the same manner ; but when the first of the series of Annual International Exhibitions was held, it was considered that they would, to some extent, occupy the place of the Exhibitions of Art-Workmanship, and, therefore, the movement was brought to an end.

Last autumn a proposal was submitted that these Exhibitions should be revived, and that medals and certificates should be offered to workmen who had designed or shared in the construction of objects of art-workmanship. The proposal was approved, and a committee was appointed to carry it into effect. The Council of the Royal Albert Hall undertook to provide space, and to assist in other ways. On further consideration, it appeared desirable that the Exhibition should be restricted to furniture alone, instead of embracing all kinds of Art-manufactures, as was the case with those formerly held, and, accordingly, arrangements were made with the following firms, by which

each firm undertook to fill a certain share of the available space:—J. G. Grace and Son; Morant, Boyd, and Blanford; Jackson and Graham; Gillow and Co.; Holland and Sons; Howard and Sons; Wright and Mansfield; Collinson and Lock; Gregory and Co.; Shoolbred and Co.; Johnstone, Jeanes, and Co. All these firms readily accepted the regulation that the prizes should be awarded not to the actual exhibitors, but to the workmen; and they undertook to assist the judges in making their awards. It was also understood that these firms would afford facilities to exhibitors of articles which might be considered as accessories of furniture, such articles being shown in company with the specimens of art furniture exhibited. Besides these, several other manufacturers of furniture, and of accessories of furniture, are showing specimens of their productions.

Without any exception, the firms above mentioned took up the matter most cordially, and the result is a most interesting and attractive collection of high-class modern furniture. All who have visited the Exhibition, speak of it in warm terms of commendation, and the Council hope that it may be the forerunner of others of equal interest in future years. Members of the Society have the right of free admission by ticket. The exhibition will remain open till the end of July, or till some time in August.

The award of medals and certificates to the workmen employed in the manufacture of the exhibits has not yet been made, but a committee has been appointed, and they have now the matter in hand.

#### XVI.—MEMORIAL TABLETS.

During the past Session tablets have been erected on six houses to mark the residences of the following celebrated men:—

James Barry—36, Castle-street, Oxford-street.

William Hogarth—30, Leicester-square.

[This house has been rebuilt for Archbishop Tenison's School.]

Sir Isaac Newton—35, St. Martin's-street.

Peter the Great—15, Buckingham-street, Strand.

Richard Brinsley Sheridan—14, Savile-row.

Sir Robert Walpole—5, Arlington-street.

In former years the Society of Arts has placed these memorial tablets on houses inhabited by Burke, Byron, Canning, Dryden, Faraday, Flaxman, Franklin, Garrick, Handel, Johnson, Napoleon III., Nelson, Reynolds, and Mrs. Siddons.

The Council have under consideration a list of houses on which such tablets might properly be put, and they would be glad to receive any information or suggestions which might assist them in selecting other suitable buildings.

#### XVII.—ARSENICAL COLOURS.

The committee, whose appointment was mentioned in last year's report, have, during the past Session, appointed a sub-committee, which carried on a careful series of investigations in order to lay down precise, and, if possible, simple instructions for testing the existence of a harmful amount of arsenic in coloured fabrics and paper. The sub-committee have prepared instructions, and have reported through the General Committee to the

Council. The report has only just been, and in a matter of so much importance, it has been thought better not to publish it has received the full consideration it on the part of the Council. The Council that the thanks of the Society are due members of the whole committee, who have constant attention to the matter, and more ally to the members of the sub-committee Heisch and Dr. Bartlett, who carried out investigations, and gave to them a great deal of valuable time.

#### XVIII.—BARRY'S PICTURES.

The well-known pictures by Barry in the Society's Great Room, being in a good condition, it was determined last year should be cleaned. They underwent a process successfully during the summer, and their appearance was much improved by the pictures have now been in the Society's for nearly one hundred years, the first exhibition of them having been made in 1834. It appears from the Society's records, they were cleaned three times previous to the last received last year, namely, about 1834, in 1863. The cleaning which they underwent was as slight as possible, the pictures only been washed over, and nothing done which would in the least degree injure the surface. The work was skilfully performed by Mr. Andrew, of the South Kensington Museum, as these paintings do, almost all the monuments of the genius of a very great artist, they deserve the greatest care that can be bestowed upon them, and it is satisfactory to report that they are in good condition likely to remain so for many years to the same time as the pictures were the decorations of the Room were cleaned and walls painted.

#### XIX.—INLAND TELEGRAMS.

It was stated in the last annual report of the Council had addressed a memorial to the master-General, asking him to reduce the rates for inland telegrams. In July last a resolution from the Council waited on Mr. Fawcett the advantage of hearing from him a statement as to the views of the Government upon the question of a tariff. It appeared, from what Mr. Fawcett said, that in the opinion of the Government there could be little doubt that a reduction of the tariff would involve, at all events, a very large reduction in the revenue, and the Chancellor of the Exchequer was in a position to face such a reduction in the revenue, there was a reason that the charges for inland telegrams be lowered. A full report of Mr. Fawcett's observations made by Mr. Chadwick and by other members of the Council appeared in the *Journal* for July 23rd.

#### XX.—SYDNEY INTERNATIONAL EXHIBITION.

The Commissioners for the Sydney International Exhibition have been good enough to inform the Society of Arts a gold medal has been awarded, in recognition of the assistance

Exhibition by the loan of Barry's painting, "The Temptation of Adam," and also in lieu of the gift of engravings and etchings by, which the Society presented to the Art of New South Wales, after they had been sold at the Sydney Exhibition.

#### XXI.—OWEN JONES PRIZES.

Prizes are awarded on the results of the competition of the Science and Art Department students of Schools of Art, for designs for carpets, etc., on the principles laid down in Jones's

prizes were offered for competition in the year, each prize consisting of a bound copy of Owen Jones's "Principles of Design," and a Medal.

successful candidates were—J. W. Riley of Art, Halifax; G. Potter, School of Art, Fanny Buckfield, School of Art, Epton; Lucie Shepherd, School of Art, Epton; James Henderson, School of Art, ; Thomas Smith, School of Art, Coal-

#### XXII.—PLANT LABEL.

At the end of last year, Mr. G. F. Wilson, F.R.S., asked the Council of the Society to undertake the award of a prize of £5, which he placed at their disposal, for the best label for plants. The object of the offer was to obtain a cheap and durable label, and thus to supply a want much felt by horticulturists. The Council accepted the duty, and led to Mr. Wilson's offer, a Society's silver

In answer to an announcement made to the effect, 120 sets of labels were sent in by the 1st day, namely, the 1st of May last. These are now under the consideration of a committee, which it is expected will soon be able to award them on their merits.

#### XXIII.—HOUSE SANITATION.

In January last, the Council published an offer of Silver Medals, for the best sanitary arrangements in houses within the metropolitan area. The medals were offered to the occupiers, or owners of the houses. One medal was awarded for a house let out in tenements to a family, for which a weekly rental is paid; one for a house of a yearly rental of from £40 or less; and one for a house of the yearly rental of £50 and upwards. In answer to the offer, six houses submitted their plans in competition, and a committee of judges appointed by the Council.

#### —SANITARY ARRANGEMENTS OF SOCIETY'S HOUSE.

It was thought desirable to examine into the condition of the drains of the house, and the inspection revealed so defective a state of things that it was determined to amend the system. This was done by Mr. E. Griffiths, under the supervision of Robert Rawlinson, C.B., on the most economical principles, and at an expense, on the whole, of £100, this sum also covering the cost of a new drainage system, which has been arranged for the convenience of members. A room on the ground floor, now a library, has been devoted to this purpose.

Messrs. Doulton were good enough to present the Society with all the necessary fittings.

#### XXV.—DOMESTIC ECONOMY.

A Congress for the purpose of promoting the teaching of Domestic Economy in Elementary Schools has been held in connection with the Society. An Executive Committee was appointed by the Council, and by their assistance an influential committee of ladies was formed, under the presidency of H.R.H. Princess Christian. This committee divided itself into sub-committees, each sub-committee dealing with one of the divisions of the subject according to the classification adopted by the Education Department.

The Congress was opened on the 20th June, by a *Conversazione* in the Royal Albert Hall, which was largely attended. The meetings for the reading and discussion of papers were held in the Rooms of the Society and in the Albert Hall, on the following days of the week. The subjects discussed included "Methods of Teaching and Examining Domestic Economy," "Needlework," "Food and Cookery," "The Dwelling," "Health," and "Thrift." As many as 56 papers were contributed under these different heads.

The following report of the Executive Committee has been received by the Council:—

1. The Executive Committee, at the last meeting of the Congress, presided over by the Countess of Derby, have the pleasure of reporting to the Council of the Society of Arts that the hopes of success entertained when the Council sanctioned the holding of a Congress of Domestic Economy in London have been fully realised.

2. The Congress was opened at the Royal Albert Hall on Monday evening, 20th June, and attracted a company numbering more than five thousand persons, the majority of whom were members of the Society. The opening was made interesting by the lighting up of the Conservatory of the Royal Horticultural Society by several systems of electricity; by the agreeable singing of children trained on the Tonic Sol-fa method; by the effective singing of the students of St. Mark's College, Chelsea; of the vocal and instrumental performances of the students of the National Training School of Music; by the playing of the bands of the Military Asylum, Chelsea, and of the Coldstream Guards.

3. The reading of papers and discussions during the Congress have been able and practical, and have been carried on daily during the week, under the presidency of the Countess of Airlie, the Duchess of Leeds, the Countess Spencer, the Viscountess Strangford, the Dowager Lady Stanley of Alderley, Lady Reay, and Mrs. Dacre Craven, ladies most experienced and accomplished for the purpose.

4. Her Royal Highness the Princess Christian of Schleswig Holstein presided at the delivery of Mrs. Buckton's lecture, and cordially expressed the knowledge and gratification she had derived from hearing it.

5. The success of this Congress is entirely due to the great and sympathetic interest which women, rather than men, have taken in it. Very few important female minds, thoughtful on women's home duties, and knowing how to teach them, have been absent.

6. The success shadows the likelihood of that forthcoming change in the Education Code, which the Congress has advocated; and confidence may be expressed that public opinion will support the Education Department in realising such necessary change.

7. Reports of the papers and discussions have been published daily, and they will be collected together hereafter. The Executive Committee recommend that some very able papers having much scientific interest, but not especially appropriate to the teaching of Domestic Economy in Elementary Schools, should be published in the Society's Journal.

8. Before the conclusion of the Congress, strong convictions were expressed by the members unanimously, that this

Congress was only the beginning of a movement for connecting the knowledge of home duties with the earliest teaching of children by women, and securing that reform of the Education Code which has been announced by the Lord President and Vice-President of the Lords of the Committee of Council on Education.

8. Accordingly, a very satisfactory beginning has been made to collect funds for preventing interruption to the work of the Congress, and for holding another Congress in 1882, when it is hoped that the plan of a National Institution, with local branches throughout the United Kingdom, may be matured and submitted to the Congress for approval. The Executive Committee have the great satisfaction of reporting that her Royal Highness the Princess Christian has expressed her gladness at continuing at the head of this movement, which is of the very highest national importance to all subjects of the Queen.

#### XXVI.—EDUCATION COMMITTEE.

In May last, on the motion of Mr. Edwin Chadwick, the Council appointed a committee to consider the question of the Education Code, and to suggest any measures of reform which, in their opinion, it might be desirable to bring under the notice of the Education Department. The committee has met once, but it has not yet reported to the Council. It is now some time since the Council have appointed an Education Committee, but reference to the back numbers of the *Journal* will show that, some years ago, when such a committee existed, it was the means of bringing before the Society much useful information on national education and kindred subjects.

#### XXVII.—FOOD COMMITTEE.

It will be in the knowledge of the members that there has long been a standing committee of the Council for the purpose of treating matters relating to the food supply of the country. The committee was formed in 1867, and for some years after its formation published the results of a number of elaborate inquiries and examinations made by its members. The committee also took a large amount of evidence on the subject of food supplies and distribution, which also was published in the Society's *Journal*. The committee have also had at their disposal now for many years a prize of £100, presented to the Society by the late Sir Walter Trevelyan, for the best method of preserving fresh meat. Though numerous methods, more or less successful, for treating meat have been before the committee, the committee have never felt themselves able to select any one as being so far superior to the rest as to deserve the award of the prize, neither have they had from any of those persons who are now engaged in the importation of meat preserved by means of cold from America or Australia any such precise claim to the credit of the invention as would warrant the committee in thus awarding the prize. The prize, therefore, still remains in the charge of the Society, and the Council would gladly welcome the advent of any process which would justify them in presenting it.

With a view of further considering this important subject, the Council have recently re-organised and enlarged the Food Committee. They have secured the assistance of a large number of gentlemen specially conversant with the subject, who will act as a General Committee, and this committee has divided itself into seven sub-committees,

which will deal with the following divisions subject:—

1. Fresh Animal and Vegetable Products and Foreign.
2. Preserved Animal and Vegetable Food at Home and Foreign.
3. Fish—fresh or preserved.
4. Drinks of all kinds.
5. Cookery.
6. Scientific questions affecting the control of adulteration, preparation, methods of preservation, nutritive and dietetic value, &c., of various kinds of food.

7. Matters affecting importation, custom, excise, revenue rates, &c., of food.

It is proposed to hold a general meeting next year, at which the actual condition of the subject may be considered, and the Council are able to announce that Professor Huxley has undertaken to preside at the meeting in the meantime, to act as chairman of the committee. The sub-committees will, it is expected, be able at this meeting each to bring up its own division of the subject, and to trust that by thus calling public attention to the matter, they may be doing useful work in the direction in which the Society has, since its formation, so frequently laboured.

#### XXVIII.—COPYRIGHT.

The Society for the Amendment of the Copyright Act have had for some time in hand a Bill for the improvement of the law of copyright. Having drafted the Bill, they applied to various persons for assistance in providing a fund to defray the necessary expenses. Inasmuch as copyright is a subject with which this Society has been associated, the existing Act on the subject having been passed through the agency of the Society of Arts, the Council felt justified in contributing ten guineas to the fund.

#### XXIX.—OBITUARY.

During the past year many notable names have been removed from the Society's list of members. In the pages of the *Journal*, so it must be, we have merely recapitulated the fact of their death.

The first on our obituary list for the past Session was the Rev. Arthur Rigg. Few men of the Society took a more active interest in the welfare than Mr. Rigg, and few were more ready to render it assistance. He gave the Society a course of Cantor lectures, and also wrote and reports for it. As a pioneer in the field of technical education, Mr. Rigg's name deserves to be remembered in this connection. G. Yapp died in November, and in him the Society lost a useful correspondent, and the Society who had often taken an active share in its work, especially in such as related to technical education. Frank Buckland was not a member of the Society of Arts, but he was well known to the Society and had frequently assisted in its work. He gave the first Juvenile Lectures of the Session given by Mr. Buckland, and he, on several occasions, read papers here, and often took part in our labours. Mr. Mishi was a valued member of the Society, and both on the Council and on various occasions

hours for the promotion of scientific agriculture are well known, and the Council are glad that, though Mr. Mechi left but a small sum for his wife and family, this is now being augmented by liberal subscriptions. Dr. Sten-  
t, who died at an advanced age in December, another member of the Society well-known in the scientific world. He, too, had read papers.

Mr. William Arnot died rather suddenly. Indeed, only a little while before his death time had been put down for the reading of a paper on his own special subject, the manufacture of paper. The members will recollect the excellent set of Cantor lectures which was delivered before the Society in 1877 by Mr. Arnot. Professor Arnot was a very old member of the Society, and a valued member. He was a frequent attendant at our meetings, and was at all times ready to whenever his special knowledge or the collection which he had formed were likely to be of use to the Society. The Earl of Caithness, who died in March, had been a member of the Society since 1851, and at one time had been vice-president.

Lord Caithness then took an active interest in the Society's work. The last time of audience at a meeting was when Professor Arnot read his first paper on the Telephone here, on that occasion Lord Caithness was the first to be at the actual working of the instruments, which operated by the distance, then thought reliable, of over a mile, between the Society's and the printing office in Fleet-street.

### XXX.—THE NEW COUNCIL.

Four senior vice-presidents, who were compelled to retire this year under the bye-law which does the constitution of the Council, were Granville, Lord Northbrook, Sir John Lubbock, and Mr. Edwin Chadwick, all of whom in different ways and on different occasions, rendered valuable service to the Society. The names of Mr. Edwin Chadwick, has, as the years are well aware, been the main promoter of schemes which have been brought forth through the agency of the Society. In their place the Council now put forward for election the names of Buccleuch, one of the oldest members of the Society, since he was elected in 1838; the Duke of Devonshire; Sir Richard Temple, whose able management of the "Forest Conservancy in India," drew so much attention when read in the Council last year; and Dr. Richardson, who was one of the retiring members of the Council. In Dr. Richardson, Mr. G. C. T. Bartley, Mr. Small Carter, Mr. Henry Doulton, and Rear-Admiral Mayne, were removed from the list, either for want of seniority or by least attendance. In their place the Council now proposes for election, Lord Alfred Hamilton, who has been off the Council for a year, whose name the Council feel sure the members will gladly see restored once more to its proper place in the list; Mr. George Matthay, F.R.S., eminent metallurgist; Admiral Sir Edward Hamlyn, C.B., F.R.S., who served once before on the Society's Council; Dr. H. Frankland, the distinguished chemist; and Mr. Loftus Perkins, who is known for his investigations in high pressure steam-engines.

### XXXI.—LIST OF MEMBERS.

There can hardly be any better sign of prosperity

than an increase in the list of the Society's members, and it is satisfactory to be able to state that such an increase has occurred during the past year. During the year 1880-81, 321 members have been removed from our list by death or resignation. During the same period 370 have been elected. There is, in consequence, an increase of 47. The total number of life and subscribing members is 3,302. There are also 37 institutions which subscribe to the Society from their own funds. This makes a total of 3,339.

### XXXII.—FINANCE.

In accordance with the Society's bye-laws, the annual statement of receipts, payments, and expenditure for the past year was published in last week's *Journal*, in order to give members the opportunity of informing themselves as to the state of the Society's finances before attending the Annual General Meeting. An examination of this statement will show that the finances of the Society are in a thoroughly sound condition, and that the Society is as flourishing as ever it was. It was stated in last year's report that earnest efforts had been made during the year then passed to pay off a certain amount of floating debt, which had been in existence for many years. This was done, and the finances having once been placed on this satisfactory footing, it now only remains to keep them in the same condition, by a careful watch over the various items of expenditure, and by equal care as regards the sources of revenue of the Society.

It may now be well to glance through the various items of the financial statement. Beginning with the debtor side, we find that the amount of subscriptions received during the year was £20,005 10s., and it is not a little remarkable that this item almost exactly coincides with the similar item of last year, £20,003 8s., there being only a difference of two shillings. The amount of life compositions last year was very high. It was £567. This year, however, it has been exceeded, for we have had £609 contributed in this way. The total receipts from subscriptions during the year are, therefore, just £42 more than they were last. Although this difference is slight, it is gratifying to see that the difference is one of increase. The amount received by the Society's dividends and interest is a little larger this year than last—£647 against £626. This is due to the additional investments which have been made by funding the life subscriptions. The next item on this side of the account which calls for remark is the advertisements. Here we are compelled to acknowledge a falling off, the receipts having been £1,457 in 1881, against £1,804 in 1880. This must be attributed to the rather stagnant condition of trade of late years, and it is to be hoped that this item of revenue will soon recover itself. The receipts from sales are about the same as last year. They include the proceeds of the sale of some of Barry's etchings. Some sets of these interesting pictures still remain in the Society's possession, and they can be sold to members at the cost of ten guineas. In this year's statement the Society has not to account for any funds which, as frequently happens, have been entrusted to it for distribution. There is, therefore, no item like the £100 received from Mr. Wetherston last year, for his prize on silversmith's work. The total receipts of the year 1881 are £23,486; those for last year

were £9,744; the difference being due to the falling off in the advertisement receipts, and to the fact that in last year's account the £100 Watherston prize above referred to appeared.

We may now turn to the credit side. Taking the items in the order set down, we find, under the first head, "House and Premises," a heavy charge for the alterations in the drainage, and for the new lavatory. This brings the total amount under this head up to £459; the corresponding head for repairs and alterations last year was £166, so that it will be seen there have been paid during the present year £338 more under this head. Although this is a heavy charge, it was a necessary one. Some particulars about it are given in the body of the Report. The item "Salaries and Wages" for the present year, is £47 heavier than last. This excess is due to a necessary addition to the clerical staff of the establishment. The charge for cleaning Barry's pictures appearing in the present statement is, of course, a special charge for this year only. The charge for stationery, printing, &c., is £53 less this year, but this is merely due to arrears of payment having been made up during 1880. The same reason accounts for the *Journal* having cost £426 more in 1880 than 1881, the total cost of this important part of the Society's operations being £2,016 this year. The charge for advertisements is £92 less this year, as was of course to be expected from the receipts from the same source being less. The examination charges show a considerable reduction this year, for they were £187 more in 1880 than in the present year. This of course is due to the alteration in the system of examinations. The Conference on Public Health, held in 1880, the payments for which were made during the financial year just ended, cost the Society £105, the similar Conference the previous year cost the Society £258, so here we find a reduction of £153. For the Domestic Economy Congress, just held, £73 have been paid; the remaining expenses for this will appear in next year's financial statement. The item for the Albert Medal deserves a word of explanation. It happens that the medal for the year before last, as well as for last year, was paid for during the past financial year, the presentation of both of them having been made by H.R.H. the President at the same time. Under the head of prizes, we find last year the Swiney Prize of £100, and Mr. Watherston's prize, also £100. There is, therefore, a difference of nearly £200, actually £195, in consequence of the new Prize for House Sanitation, on which some small expenses have been incurred. The amount spent on Cantor lectures this year is £10 less than that spent last. These charges are defrayed, as the members are aware, out of funds left by Dr. Cantor to the Society. The National Training School for Music again appears for the sum of £164, but it is not expected that any charge under this head will recur. The Art-Workmanship Exhibition is down for the small charge of £5. The principal charges for this will appear next year; it is not supposed that they will exceed some £50. In last year's statement, we find a sum of £196 put down for payments on account of the Artisan Reports on the Paris Exhibition of 1878. This being the last payment in this matter, there is, of course no corresponding item in the present year's statement. The total amount expended by the

Society was £8,716; the amount last year, £9,297. It will thus be seen that in the year there has been expended £581 less year.

We now proceed to consider the liabilities of the Society. Here, again, a very satisfactory state of things. The assets over liabilities last year was £7,731; present it is £8,617, showing a difference in good of £882. Amongst the liabilities, the men's bills, due at the present time, are more than last year. The alteration in the system has reduced the amount due to Examiners from £188 in 1880 to £54 in the present year, the difference being £134, while the £42 of liabilities for two medals in the 1880 have been paid, and therefore no liability at present under this head. As to the assets, our invested funds have been from £3,571 in 1880, to £4,344. The sum of the year uncollected are £61 less year—£749 against £810; while it is significant, also, to note that the arrears are quite so heavy, and may be estimated at £300, instead of £350. The proper Society is put down at the moderate sum of £2,000. The same cause which has reduced actual earnings for the *Journal* advertisement during the year has also lowered the down as an asset under this head. We expect to obtain £1,256 which we may expect to obtain £1,477 last year. The Trust Funds in the Society are set out at length in the statement. The principal of these is Dr. Cantor's bequest, £5,052, the interest of which is to the popular Cantor lectures. The amount is the bequest of Dr. Cantor, £4,500. This is chargeable with the sum of £200 once in five years, £100 of which is expended upon a silver goblet, and the other £100 is presented with the goblet to the author of published work on Jurisprudence. The bequest is £1,800. The income of this is applied for the general purposes of the Society. The following Trust Funds are charged with the award of medals or money prizes out of the interest resulting from them:—

John Stock .....	£100
Benjamin Shaw .....	£100
North London Exhibition .....	£100
Fothergill .....	£100
Dr. Aldridge .....	£100
Thomas Howard .....	£100
Owen Jones Memorial .....	£100

The Mulready Trust of £109 is charged with the expense of preserving in order the portrait of the artist in Kensal-green Cemetery. The subscriptions for the Memorial Window at Paul's Cathedral, £345, is being collected by the Council until some decision on the subject has been arrived at. The amount of £100, prize by the late Sir Walter Trevelyan above in the section of the report dealing with the Food Committee, has been placed on the list of Messrs. Coutts. There is also an amount of £50 given by Mr. Murray as a building fund.

man, in moving the adoption of the report, some of the chief points contained in it. He the award of the medal to Dr. Hofmann the greatest satisfaction both in Europe and America. As to the Patent Bill, now being could not say that they would be able but it would go forth as a Bill which the night ought to be passed. He must acknowledge was horrified at the particulars which were the meetings of the Committee on Poisonous here he learned that the green of the ordinary inds was often obtained by the use of arsenic nt, and that, after having been dried by ess blinds threw off a considerable amount l dust to poison the air of the room. He the members present, with regard to the the walls, that no mother washed her rith greater care than was taken by those ook the responsibility of cleansing Barry's He then made a few remarks upon the reduc-price of telegrams, upon house sanitation; to the Food Committee, of which Professor consented to act as chairman, said that any which that gentleman was connected was ood work. In conclusion, he expressed the the details given under the head of finance, the items of receipts and expenditure in many who found some difficulty in understanding a balance-sheet.

#### SECRETARY.

H. Trueman Wood, B.A.

Mr. Liggins thought the reason why these annual meetings were not more fully attended, was that members were quite satisfied with the conduct by the Council of the Society's business. He then drew attention to Mr. Hyde Clarke's letter in the *Journal* of June 10, on the "Manufactures, Trade, and Progress of England," and suggested the appointment of a committee by the Council on this subject.

Mr. Christopher Cooke referred to the erection of memorial tablets, and suggested some additional houses upon which they might be set up.

Mr Hyde Clarke urged that some action should be taken to preserve the trade which was being wrested from Englishmen by foreigners, and that more attention should be paid to British commerce abroad. He thought a committee appointed by the Council might do much for the improvement of the present state of manufactures.

Mr. Christian Maat supported Mr. Clarke's proposal, which he considered to be one of the greatest importance.

Mr. Pfoundes said that he considered this a most practical proposal; and from his own experience he could say that, if the suggestion was carried out, the members of the Consular service would be greatly helped by such action.

Mr. Pagliardini thought that Mr. Clarke should read a paper on the subject early next Session. He also suggested that a tablet should be erected on the house, No. 20, Bentinck-street, where Gibbon wrote his history.

Mr. Hyde Clarke could not agree with Mr. Pagliardini, as he considered his proposal was one to which immediate attention should be given.

A vote of thanks to the Scrutineers, moved by the Chairman, and seconded by Mr. Rumsey, was carried unanimously.

A vote of thanks to the President, Vice-Presidents, Council, and Officers (especially to the retiring members of Council and to the Chairman), proposed by Mr. Hyde Clarke, seconded by Mr. Hale, and supported by Mr. Campin, was carried unanimously.

Mr. Bramwell returned thanks, and the meeting adjourned.

#### MISCELLANEOUS.

#### NOTES ON GUMS, RESINS, AND WAXES.

By C. G. Wernford Lock.

The following economic notes, from the journals of recent travellers, seem worthy of reproduction in a collective form:—

*Senegal Gum*.—The product of acacias which grow

in the neighbourhood of the Sahara. During the harmattan winds, the gum exudes from the bark of the trees in tears, and solidifies in the open air, the amount of exudation depending upon the force and duration of the wind. The production in 1871 was 3,161,906 kilo. (of 2·2 lb.).

*Mpafu*.—A large tree yielding a sweet-scented gum-resin, much valued by the natives on the Victoria Nyansa.

Gum *Arabic* is produced by *Acacia gummifera* (*Mimosa gummifera*, *Acacia coronillifolia*, *Mimosa coronillifolia* *Sassa gummifera*), a scarcely known plant of Morocco, occurring abundantly as a thorny bush in the lower region of south and west Morocco, according to the testimony of the natives, who call the plant *alk ilah*. The gum does not seem to be collected in the western portion of its range in south Morocco, but in Demnet, whence it is carried to Mogador. Possibly it is only in the hotter and drier regions of the interior that the gum is produced in quantities to be worth gathering. At any rate, its gum is yielded only during the hot, parching months of July and August, and increases according to the hotness of the weather and the sickly appearance of the tree, being least after a wet winter and in a mild summer.

Some accounts suppose the Moroccan gum *Arabic* to be derived from *Acacia arabica*, which is found in Senegal; but all the inquiries made by Consul R. Drummond Hay, for Hooker and Ball, agree that this plant, the *alk awerhal* of the Arabs, is not found in Sus, no such tree existing either north or south of the Atlas Mountains, its gum being brought from Soudan, and of inferior quality to that of *A. gummifera*. It is further stated that this latter species grows chiefly in the provinces of Blad Hamar, Rahamma, and Sus.

*Elsini*.—This used to be brought in large cakes to Bembe (West Africa), and is said to be very abundant at not many days' journey.

*Jutahy-seca*.—A resin or gum which exudes from the bark of the jutahy tree of Brazil (*Hymenaea mirabilis*); universally employed for varnishing native pottery.

*Copal*.—Red gum copal is almost entirely the product of the Mossulo country (Angola), though it exists farther north, as at Mangué Grande. Until 1858, it was a principal export from Ambriz to America, but the war stopped it. According to native accounts, it is found below the surface of a highly ferruginous hard clay, at a depth of a few inches to two feet. It probably extends much deeper, but the natives are too lazy to look for it. It occurs in irregular flat masses up to several lbs. The natives only dig for it during and after the last and heaviest rains in March—May, and restrict the export to maintain the price. No trees and but little grass grows over the spots. The tree is said to be abundant in the woods adjoining the inner side of the wilderness in Usambara (East Africa), but does not extend farther inland.

A great staple of the district traversed by the newly-made road from Dar-es-Salaam, through the Wazamara country, is gum copal, which is found in many parts. This fossil resin seems to exist, even in the richest diggings, only in patches, as though it were produced by isolated trees. The natives appear to work the country nowhere systematically; they sink test-holes, and, on finding traces of the resin, work that part thoroughly. In many places, test-holes have been made and the place abandoned as useless, although not far off a patch has been well worked. The fossil resin, now found underground usually in red sandy soil, is undoubtedly the produce of the same species of tree as still exists in these jungles, and which now yields an inferior sort of resin. The difference between the two products seems to arise from chemical or molecular change effected by time. The copal tree grows throughout the Uzamara country, and is by no means confined to the sea coast, but is even more abundant inland beyond the first coast-ridge. It is not seen, however,

where the old limestone formation of the interior shows its appearance.

*Chian Mastic*.—The mastic country of Chian is flat and stony, with little hills intervening in rare streams. Rain is destructive of the mastic; it is rare, but much to be feared. The resin is of *Pistachia lentiscus*. The principal villages in the industry are Calimassia, Saint George, Anabato, Nénita, Meeta, and Kalamoti, but there are about a dozen of minor importances. Mastic occurs in white grains, varying in size from the head of a pin to the height of a pea. The shrubs yielding it are of the height of a man. It occurs also in Al Arabia, but always of inferior quality, though the reason has yet been adduced for the July—August, a great number of incisions in the stems of the shrubs, and renewed the times. Repeated visits are then made to resin which exudes. A shower of rain in the period produces disastrous results, by washing the resin. There are four qualities of mastic: (1.) Mastic is composed of large pieces, and is considered by connoisseurs; it is sold chiefly for seraglios, all Turkish women chewing mastic is 120 to 130 piastres, and even more, per gram. (2.) Mastic in large tears is worth piastres ordinarily. (3.) Mastic in small tears is worth 70 to 85 piastres, and is used industrially mixed with fragments of leaves and to make so-called "mastic brandy," the Turkish liqueur, called *raki*. It is made mastic in the brandy obtained from dry distilling the product, and flavouring with sugar. The best qualities of mastic are from the Levant; Europe imports the inferior grade varnish.

*Chian Turpentine*.—Afforded by *Pistachia*. That which exudes from the shrub is very aromatic, but the quantity is very limited.

*India-rubber* (from *Ficus elastica*).—The rubber in Assam is conducted underground in the case of all trees growing in the timber but cannot be enforced on scattered trees. The rubber plantation has an area of 80,000 acres. The exports from Lakhimpur in 1871 were valued at £8,340. Immense forests of these trees on both banks of the Subansiri river, and on one but the reckless treatment they receive lessees of the forests caused their ruin. The leasing of these forests ceased, but there is no rubber left in the plains of the Lakhimpur. The tree grows to heights of 15 to 35 feet, when fit to be tapped, is 18 inches to 6 feet in diameter. The yield for the first tapping of a tree is 3 to 4 lbs. of rubber. It is then allowed to remain for three or four years, when another collection is made, but the yield is then much less. It is the forests of Cachar could yield upwards of 100 lbs. of rubber annually. It is stated that the most during the rains.

Of india-rubber, 20,000,000 lbs. are reported from Pará (Brazil), chiefly from *Siphonia elastica*, but a few other species exist. The utmost yield from each tree is one pound of rubber in the wet season, from February to July, when the tapping is stopped. The tree on the *terra firme* when planted, but naturally lodge in lowland swamps. It is planted and cared for yield well in Brazil is being gradually cleared of gatherers now go to the Tocantins, Madeira, Rio Negro, and will soon clear there also. The method of preparing rubber, instead of dropping the milk into alum solution; it is superior, but is not adopted.

India-rubber plants grow on the Cameroons mountains (West Africa), but

know their value. India-rubber trees be River Djour, in the province of Bahr el the natives of the Marutse-Mabunda the Upper Zambesi, trade in india-rubber trees to the west.

*Lelechia* vine is known from Pangani inland to Handei (in Usambara, East Africa), and the rubber is made into balls for export.

creeper, *Landelphia*, grows chiefly on trees and streams in Angola and the Congo. exudes a milky juice when cut or wounded, but not run into a vessel placed to catch it, as quickly as to form a ridge on the wound, its further flow. The blacks collect it by cuts in the bark with a knife, and as the gushes out, it is wiped off continually, and smeared on their arms, shoulders, till a thick covering is formed. This is air bodies and out into small squares, which is to be boiled in water. From Ambriz the rubber quickly spread south to the River are considerable quantities are exported.

0 miles of the coast from Liawa and the y (Massai and Rovuma, East Africa) the trees almost entirely formed of india-rubber, ing an abundant supply of fine india-rubber, athered only in a very desultory manner by who gash the plants, and collect the rubber in a liquid form, and dries hard after short the air. Rolled into orange-like balls, it is id, where what is worth 7 to 8 dols. fetches width of the belt is 15 to 20 miles. On Lake (Central Africa) are one or two kinds h produce caoutchouc of good quality.

has just determined, with accuracy, the yields the best East African india-rubber, ained seeds of the species for introduction

It occurs in great abundance along the road from Dar-es-Salaam, in a west-south- section, for about 100 miles towards the ast Africa, through the Wazamara country; itly but little affected, except in the imme- bourhood of the villages, by the reckless oping employed. In many parts, a native lect 3 lb. of rubber daily. There are five only one is considered worth tapping.

*id Guttas of Borneo and Suva*.—The Kadyans rut neighbours collect a quantity of gutta- ndia-rubber in the surrounding forests. The erwards manufactured into lumps or balls, d to Labuan for sale. The gutta is obtained five species of the genus *Isonandra*, all large

The trees are felled and their bark is inged at intervals of two feet, the milky being caught in vessels formed of leaves or lls. The crude juice is hardened into slabs boiling, and is generally adulterated with of scraped bark. Indeed, it is said that the lers, who buy up the gutta from the ould refuse the pure article in preference for ing bark, to which the red colour is mainly

ber in the north-west districts of Borneo is of three species of climbers, known to the *nanoongan*, *manoongan putih*, and *manoongan* air stems have a length of from 52 to 100 iameter rarely exceeding 6 in.; the bark is and coloured grey or reddish-brown. The blong, green, and glossy; the flowers axillary clusters, and are succeeded by , of the size of oranges, and containing seeds eans, each enclosed in a section of apricot- t. These fruits have a delicious flavour, h prized by the natives. The stems of the creepers are also cut down to facilitate the the creamy sap, which is afterwards to rough balls by the addition of nipa salt.

The fallen gutta trees lie about in all directions in the forest, and the rubber-yielding *Willughbeias* are also gradually, but none the less surely, being exterminated by the collectors in Borneo, as throughout the other islands, and on the Peninsula, where they likewise abound.

It was formerly thought that gutta-percha was the produce of only one species of tree (*Isonandra Gutta*), but that obtained from the Lawas district is formed of the mingled saps of at least five species, the juices of a *Ficus*, and of one or two species of *Artocarpa*, being not unfrequently added as adulterants. The Bornean gutta *soosoo*, or india-rubber, again, is the mixed saps of three species of *Willughbeia*, with the milks of two or three other plants surreptitiously introduced to increase the quantity.

The gutta trees are slow to attain maturity, and are difficult to propagate, except from seed. The *Willughbeias*, on the other hand, grow rapidly, and readily lend themselves to both vegetative and seminal methods of propagation; hence these are especially deserving of the attention of the Government of India, where they may reasonably be expected to thrive.

There are, doubtless, yet many thousand tons of rubber and gutta in the Bornean woods, but as the trees are killed by the collectors without any thought of replacing them, the source of supply must recede constantly farther from the markets, and prices will rise in consequence. The demand for india-rubber from Borneo is of quite recent growth, yet in many districts the supply is already practically exhausted.

In Assam, Java, and Australia, rubber is afforded by *Ficus elastica*, which is cultivated for the purpose. There are many milk-yielding species of *Ficus* in the Bornean forests which, with careful experiment, may possibly be made to contribute remunerative quantities. The Malayan representatives of the bread-fruit family also deserve examination, as an excellent indiarubber is derived from *Castilleja elastica*, a South American plant of this order.

*Lac*.—Secreted by an insect (*Coccus lacca*), on the branches and twigs of certain jungle trees, principally *khusum* (*Schleichera trijuga*), *plas* (*Butea frondosa*), and *bier* (*Zizyphus jujuba*). The lac from the first is more esteemed than that from the others. To some extent, the lac is found occurring, so to speak, spontaneously, and is collected by forest tribes, and brought by them to the fairs and bazaars for sale. Where, however, there is a regular trade in stick-lac, propagation of the insect is steadily carried on by those who wish for a certain and abundant crop. This propagation is effected by tying small twigs, on which are crowded the eggs or larvæ of the insect, to the branches of the above-named species of trees. These larvæ are technically called seed. The larvæ, shortly after sowing, spread themselves over the branches, and, taking up position, secrete around themselves a hard crust of lac, which gradually spreads till it nearly completes the circle round the twig. At the proper season, the twigs are broken off, and on arrival at the factory, are passed between rollers, which admit of any degree of approximation. The lac is thus crushed off, and is separated from the woody portion by screening. It is next placed in large tubs half full of water, and is washed by coolies, who, standing in the tubs, and holding on to a bar above by their hands, stamp and pivot about on the heels and toes, until, after a succession of changes, the resulting liquor comes off clear. The lac having been dried, is placed in long cylindrical bags of cotton cloth of medium texture, and about 10 ft. long and 2 in. in diameter. These bags, when filled, are taken to an apartment where there are a number of open charcoal furnaces. An operator grasps one end of the bag in his left hand, and slowly revolves it in front of the fire; at the same time, an assistant, seated at the other end of the bag, twists it in the opposite direction. The roasting soon melts the lac in the bag, and the twisting

causes it to exude, and drop into troughs placed below, which are often only the leaves of *Agave americana*. When a sufficient quantity in a molten condition is ready in the trough, the operator takes it up in a wooden spoon, and places it on a wooden cylinder, some 8 to 10 inches in diameter, the upper-half of which is covered with brass—in some places the freshly-cut, smooth, cylindrical stem of the plantain is used for this purpose. The stand which supports the cylinder gives it a sloping direction away from the operator. Another assistant, generally a woman, now steps forward with a strip of *agave* in her hands, and with a rapid and dexterous draw of this, the lac is spread at once into a sheet of uniform thickness, which covers the upper portion of the cylinder. The operator now cuts off the upper edge with a pair of scissors, and the sheet is lifted up by the assistant, who waves it about for a moment or two in the air, till it becomes quite crisp. It is then held up to the light, and any impurities, technically "grit," are simply punched out of the brittle sheet by the finger. The sheets are laid one upon another, and, at the end of the day, the tale is taken, and the chief operator is paid accordingly, the assistants receiving fixed wages. The sheets are placed in packing-cases, and when subjected to pressure, break into numerous fragments. In the fresh state, the finest quality has a rich golden lustre.

The dark-red liquor before referred to, as resulting from the washing, is strained, in order to remove all portions of woody fibre and other foreign materials. It is then passed into large vats, where it is allowed to settle; the sediment is subjected to various washings, and at last allowed to settle finally, the supernatant liquor being drawn off. The sediment, when of the proper consistency, is placed in presses, from which it is taken out in the form of hard, dark-purple cakes, with the manufacturer's trade-mark impressed upon them. This constitutes what is known as lac-dye. The dye which is thus separated from the lac by washing is said to be the body of the insect—not a separate secretion.

It might appear that some mechanical arrangement would be more efficacious and economical for washing and separating the lac from the dye, but human labour is so cheap, that this is not the case. The daily pay of the women is 1d. to 1½d.; of the men, 1½d. to 2d. No evil effect on the feet of the stampers is to be observed. The great and sudden oscillations of price in the London market render this trade very risky, and the aniline dyes have well-nigh rung the knell of lac-dye in European industry.

In Assam, a small quantity is produced in the district of Darrang. In some districts, the insect is artificially reared on the *jhuri* tree (*Ficus cordifolia*).

*Indian White Wax*.—This is produced by the female of the *Ceroplastes ceriferus*, an insect allied to the *Pala* of the Chinese, whose product is so largely used for making candles for the Buddhist temples. The Indian insect deposits its wax in small masses upon the twigs and branches of several trees, but more particularly on the *arjun* (*Terminalia Arjuna*); it does not appear to have ever been propagated, nor has the wild product been collected in quantity. Though an article of undoubted value, it would perhaps scarcely repay expenditure of European time and capital; but the natives might surely render its cultivation a very profitable undertaking. The wax is soluble, or nearly so, in boiling alcohol, also in benzine and ether, but only very slightly in turpentine and carbonic disulphide ( $CS_2$ ). Its composition is  $C_{11}H_{14}O$ . It is found at many widely-distant points throughout Sirguja, and is abundant, and suitably situated for experimental cultivation, on the *arjun* trees growing upon the embankment of the Purulia lake.

*The Gum Trade of Somali Land* (East Africa).—The gum, or *habak*, always sold in grades, bears the name of *ambab*. On sifting, it is always found mixed with a

small quantity of other sorts which make wei balance; these are the *habak cuddi* and the *ha*. The incense, or *luban*, sold in grades, takes the *beiho*. The *saphi*, or "triage," is divided qualities. The 1st, *fasous*; the 2nd, *nagous medjigel*. The *saphi*, or "triage," is made in when the arrivals are not too great, by children, who are paid about 6d. a day.

The myrrh has but one quality, but it is n be on the guard against the admixture of fi of the same colour, but more powerful odour, Arabs call *addi*. It is easy to recognise which always appears oily.

The *maid*, called in Europe "gum elemi, of incense in large bleached tears. It presen grades as incense, and buyers aim especially ing the tears unbroken to heighten the value

The *alet*, or *mouroud*, is a grey gum exquisite odour recalling that of ambergris.

The *addi*, or false myrrh, whose odorifero mixed with the wood of *djirmeh*, has an o burnt closely resembling that of "seraglio p

The *fallah-fallah* is a resinous bark, which give off a peculiar odour, under the name of

Haffoin, in 1877, received 25 bohars.

Magnificent incense-trees, two to three feet are found on the lofty mountains toward coast of Somali Land. Mareyeh, an village, lying over 30 miles west of Cap has a large export of myrrh and incense.

Obeidh, the capital of Kordofan, is the large trade in gum, which is collected in tl the women and children, and taken to the where it is disposed of to petty itinerant ultimate dispatch to Europe.

*Moroccan Gum Ammoniacum* (which must founded with the Persian product of *Doreum*, or *ushak*), is an object of commerce v and Arabia, where it is employed, as of ol gating. The plant affording it is called Arabic, and has been hitherto referred to *Ferul* or *F. tingitana*; but Ball and Hooker consider it an *Elaeagnus*, probably *E. humile*. Leared that this plant grows at a place two days from on the Morocco road; but Hooker and Ball w that it is found nowhere along that route, no it than El Araiche, a place lying north of Me which is confirmed by information gather Drummond Hay, to the effect that it c Morocco, and chiefly around Teda.

*Gum Sanderach* is a product of *Cultiris g* (*Thys articulata*, *Fraxinus Pentanensis*), a tree l

mountains of North Africa, from the Atlantic to Algeria, its eastern limit being undetermined. It is, once a reputed medicine, is collected by the Arabs and exported from Mogador to Europe, where used in varnish-making.

Shortum gum is produced by *Euphorbia resinifera*, confined to the interior of Morocco. The juice from incisions made with a knife, and hardens drops off in September, the produce being used only once in four years. The people who collect smudge the cloths over their mouths and nostrils, to keep the small dusty particles, which provoke intense sneezing. The gum once had a wide medicinal use, but made in it is now rapidly declining, and its consumption is restricted to veterinary practice, and as an ingredient in a marine paint.

#### CASTOR OIL GAS-WORKS AT JEYPORE.

Report by Major S. B. Jacob, on the Jeypore Oil works, an establishment founded by the late Maharajah of Jeypore, is quoted in the *Journal of Gas Supply*. From the memorandum on the working of the establishment prepared by the present manager (Mr. Tallery), whose administration is highly commended by Major Jacob, it appears that the gas is gally produced from castor oil, with the addition, the castor seed is not available, of poppy, til, or seed. According to Mr. Tallery's own records, he

uses from one maund of castor oil (82 lbs.) about 750 feet of 26½-candle gas; or 1,000 cubic feet of 18½-candle gas; or 1,250 cubic feet of 9-candle gas. With the same quantity of material worked to make equal quantities will produce 610 cubic feet, 762 feet, and 914 cubic feet of the respective grades emitting power. According to these results, taking present prices of oils delivered into the works—castor oil Rs. 11 12a. (22a. 4d.), and the other oils Rs. 10 10d. per maund—the castor oil gas is Rs. 0 10a. 4p. d. per 1,000 cubic feet cheaper than other oil gas. Castor oil is double in all respects, duplicate sets of machinery, purifiers, &c., and gas-holders being erected, for the arrangement no reason is given. At present two small retorts are used, which are kept at work about 215 hours per month, and produce some 98,720 feet of gas in this time. Worked in this way, the cost of manufacture (exclusive of the cost of gas) is as follows:—

	Rs.	a.	p.
Wear and tear .....	1	3	3½
Fuel .....	2	11	7
Labour .....	0	5	3½
Purification .....	0	0	4½

Total cost per 1,000 cubic feet ..... = Rs. 4 4 4½, or Rs. 4d.

High charge for manufacturing expenses is said to be the fact of so little gas being required; if the consumption should increase to about 260,000 cubic feet monthly, which could be supplied without increased establishment charges, the working expenses per cubic foot would be reduced to Rs. 2 9a. 5½p. (5a. 1d.). Gas is chiefly consumed in the public offices and houses; there are, however, a few private consumers, who are charged by meter at the average cost price, Rs. 1a. 6p. (3a. 10d.) per 1,000 cubic feet, and are well satisfied with the supply. Most of the gas is consumed only 1½ cubic feet of gas per hour, which, with this rate of consumption, is equal to 17 to 18 candles; the gas is therefore of high quality. The street main from the works is 6 inches diameter, which is considered ample for supplying houses. One house in Jeypore has 115 lights fed through an inch service-pipe. The loss by gas is estimated at about 15 per cent. The supply

of premises temporarily, or when situated at a distance, is provided by compressing gas at the works to about three atmospheres by means of a pump driven by one bullock. The compressed gas is then delivered in a wrought-iron receiver to the point of consumption, where it is either transferred into fixed receivers and burnt by the aid of suitable regulators, or is delivered into small portable or service gas-holders, and burnt in the usual way. A gas, or landing-stage, two miles distant, is thus supplied with 400 cubic feet of gas every day, which is consumed by 30 jets, each burning 1½ cubic feet per hour for nine hours. There have not been any accidents from the distribution of gas in the portable reservoirs, or otherwise. As railway carriages are also supplied with compressed gas, it is evident that the introduction of this branch of service has widely extended the utility of the establishment. Another peculiarity of the Jeypore undertaking is the necessity that exists for the manager to unite the attributes of a farmer to his other acquirements, for the purpose of securing a constant and cheap supply of raw material for gas-making. Last year Mr. Tallery personally superintended the sowing of 300 acres with the castor plant (*Ricinus vulgaris*), and the establishment includes a hydraulic oil-pressing apparatus. The process of extracting the oil for carbonising is as follows:—First, the castor seed is passed through the crusher, when the shells only are broken off. The shells are then picked out by hand, and the seed is again introduced into the crusher, where it is ground to a paste. It is then passed into the heating pan, and, after being well heated it is packed into horsehair bags and filled up hot into the press immediately. After about 20 minutes' pressing, the extruding oil being meanwhile collected, the cake is removed and ground over again. It is subsequently heated and pressed a second time, until about 33 or 40 per cent. of oil is obtained from the seed. The labour of preparing and pressing the castor seed costs Rs. 1 1a. 6p. (2a.) per maund of oil. The cost of extracting other seed oil is about the same, with the exception of the cost of removing the shells. For generating gas, the oil is used as it comes from the press. Formerly, at other places, when the oil-bearing seeds were carbonised for gas without previous treatment in this way, the product was overloaded with carbonic acid from the woody part of the seeds, and correspondingly heavy cost for purification was incurred, which by Mr. Tallery's process is entirely avoided. When the establishment was first started, the cost of manufacturing gas was Rs. 23 3a. 5½p. (45a. 10d.) per 1,000 cubic feet; but from the time when the present manager obtained full powers of working independently the cost has been reduced, over an average of six months' working, to Rs. 18 1a. 6p. (35a. 10d.) per 1,000 cubic feet. There will be considerable saving if the manager succeeds in his castor plantation, and he is confident that during the next twelve months the cost will be brought down to Rs. 13 or Rs. 14 (25a. 9d. to 27a. 9d.). The illuminating power of the gas is such, that a burner consuming 1½ cubic feet per hour is equal to 17 or 18 candles, and about 800 cubic feet of purified gas are usually produced from a maund of oil. As a further means of economy, it is proposed to erect an apparatus to burn the tar, which is rather a drug, for the preparation of lamp-black. This is expected to bring in a better profit than the present system of selling the tar at an almost nominal price.

#### MANILLA HEMP.

The following is a report from Surgeon-General Balfour to the Secretary of State for India, dated October 16, 1880:—

"Mr. Liotard, of the Agricultural Department of the Government of India, has this year (1880) reported on the materials in India, suitable for the manufacture of paper. Several of the fibre-yielding plants are mentioned

by him, and, amongst others, various species of the genus *Musa*, of the plantain or banana tribe, many of which have been grown in the East Indies from the most remote times. At pages 64 to 68, he describes the introduction, in February, 1868, of the Manila hemp plant, direct from the Philippines, into the Madras districts, by Colonel (now Sir George) Balfour. Nevertheless, the Import Trade Returns of the United Kingdom show a large and continually increasing delivery of hemp from the Philippine Islands, now averaging yearly about 20,000 tons, valued about half a million sterling. I have ascertained from the London produce brokers, through Dr. Birdwood, of the India Office, that this important article is the true Manila hemp from the *Musa textilis*, that the bulk of it is delivered in London, where it is made up into cordage and ropes for ships, especially for yachts' running rigging, being very light, strong, and clean, and also for clothes lines. But there is no doubt that the Manila hemp plant, *Musa textilis*, grows as well in British India as other species of the plantain or banana genus, and that British India could, in a couple of years, supply the London market with all that it could take of Manila hemp fibre. The prospect of benefiting British India by creating an export trade from it of the extent and value above indicated might well incite to considerable efforts to attain success. In 1861 to 1863 the Madras Revenue Board made continuous efforts to secure the naturalisation of the plants which Colonel Balfour had introduced, but their efforts seem to have been effectual only in the Wynnad, from which, by 1877, the Conservator of Forests replied that the Philippine variety had been introduced on several of the coffee estates, where it grows remarkably well, and no doubt is felt there as to the value of its fibre. The attention of the Boards and Commissioners of Revenue, and of the Agri-Horticultural Societies might be re-directed to this plant."

### STEAM DIGGER.

Where labourers and workmen are continually striking for an increase in their rate of wages—even when, as has occurred recently at Goulburn, N.S.W., they are in receipt of no less than 12s. per day of eight hours—it is not surprising that mechanical inventiveness is stimulated in its efforts to supplant manual labour by machinery. One of the most recent evidences of activity in this direction is the "steam digger," which, first making its appearance at the Carlisle Show of the Royal Agricultural Society last year, has since then been subjected to practical trial. The inventors claim that the steam digger can dig an acre of ground in one hour at a cost of 6s.; in other words, that it can do work equal to the labour of 170 men in a day, or of one man in seven months, which labour would, at ordinary rates represent an expenditure of £21. Compared with the cost of ploughing, the digger gives the following results:—To plough ten acres in one day with the familiar horse-plough would require ten men and ten boys and thirty horses, at a cost of £8, and the estimated cost of similar work with the steam-plough is £4 5s., while the steam digger undertakes to perform the same amount of labour for £2 7s. It is also claimed that the machine produces superior cultivation, and that the "motor," when not employed in digging, may be

used for other farm purposes, such as threshing and grinding. Recent public trials of the steam show that the machine will dig to any depth & foot. In working, a number of sharp-points are set in motion, digging into the earth and over the soil as cleanly and evenly as the most labourer. A space twenty-one feet in breadth a time; but the machine, when travelling on roads, can be turned round "end on," and any ordinary thoroughfare. On the vast area in Australia, Canada, Cape Colony, New Zealand, other of our colonies where labour is scarce machine would be invaluable. It is equally on wet, dry, or even frost-bound soil.—*C. India.*

### GENERAL NOTES.

**International Medical and Sanitary Exhibition.**—This Exhibition, organised by the Committee of Museum of Hygiene, will be opened on Saturday and continue until August 13. The opening ceremony takes place in the Royal Albert Hall, at 4.30 p.m. presided over by Earl Spencer, Lord President of

**New Zealand Wool.**—The total quantity exported from New Zealand in 1879, amounted to 62, of the declared value of £3,126,438, against 59, of the declared value of £3,292,807, exported increase of 2,950,554 lbs. in quantity, and a £188,368 in declared value. The exports for the years, ending respectively on the 30th September follow:—

Year ending 30th September.	Wool in
1879 .. .. .	42,23
1874 .. .. .	47,42
1875 .. .. .	49,94
1876 .. .. .	55,97
1877 .. .. .	56,52
1878 .. .. .	62,16
1879 .. .. .	62,64

The wool produce for 1879 only amounted to more in weight than the produce for 1878. The wool production has been seriously checked increase of rabbits in some parts of the colony.

**Mining Accidents in Victoria.**—It appears report of the Chief Inspector of Mines in Victoria year 1880 that the total number of accidents during was 134. The proportionate number of persons those employed in and about mines has been compared with 1.29 per thousand in 1879, and 1.93 in 1874 (the first year in which a "Regulation Statute" came into operation). The following the number of accidents in the last seven years, with the mining population of the colony during period:—

	Mines Employed.	Accidents.	Killed.	Injured.
1874 ....	48,512	296	80	345
1875 ....	42,068	275	83	217
1876 ....	41,581	209	55	179
1877 ....	56,960	213	64	154
1878 ....	57,212	121	40	106
1879 ....	57,195	144	48	112
1880 ....	59,978	134	50	80

**Royal Society of Literature.**—Mr. T Saunders will read a paper on Wednesday, July 27th, before this society, on "The East of Palestine."

## AL OF THE SOCIETY OF ARTS.

No. 1,494. Vol. XXIX.

FRIDAY, JULY 8, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.O.*

## NOTICES.

## ART FURNITURE EXHIBITION.

Exhibition of Works of Art Applied to Furniture, in connection with the Exhibition of Works of Art at the Royal Albert Hall, is now open. A non-transferable season ticket will be issued to any member of the Society on application to the Secretary. A ticket, to admit two persons, will be issued with the present *Journal*.

## MEETINGS OF THE SOCIETY.

## CANTOR LECTURES.

## WATCHMAKING,

By Edward Bigg, M.A.

I.—DELIVERED MONDAY, FEB. 7, 1881.

*Topics—Units of time—Historical sketch—Evolution of usual forms of watch—Escape-ment—Conditions of accurate timekeeping, and the elements necessary for their maintenance in the higher class of watch.*

I was invited by the Secretary of the Society of Arts to deliver a course of Cantor Lectures on Watchmaking, it was with much reluctance, but some diffidence, that I undertook it. I felt, as any who thought of the subject must have felt, that some prominent person of the trade, who had spent a good many years of his life in that industry, and whose views on the subject were therefore more entitled to the attention of the Society, could with greater propriety occupy the position in which I find myself; at the same time, I am sanguine enough to think that, in endeavouring to bring the subject before a non-technical audience, it may be possible to draw the attention of such watchmakers as are present, or who may read these lectures, to certain questions that appear to require further consideration.

It often seemed to me to be a matter of surprise that the public take so little notice of this important mechanical art, an art in which we are all directly interested, and which, in

its highest perfection, has long had a home in this country. The true watchmaker has far more to do than to make a piece of jewellery; and in many ways his work possesses even more interest than that of the engineer; by watchmaker, however, I would not here be understood to mean anyone and everyone who chooses to so designate himself, but one who, besides possessing great manual skill, is able to so combine the several parts of the watch, analysing the subtle phenomena that occur, taking cognisance of the minutest mechanical effect, and calculating its proportions, that he may secure the highest excellence in timekeeping; and, added to all this, he must possess an artistic instinct enabling him to impart a graceful appearance to the mechanism. And yet how many there are whose appreciation of the watchmaker's art is limited to a remark on the delicacy of the parts, and the skill of touch and sight that they indicate. A well-finished machine, or even a piece of high-class cutlery, will not unfrequently be more likely to command attention. It may undoubtedly be said that none but those who make it the business of their life to adjust high-class clocks, watches, and chronometers can appreciate the mental labour that has been expended in bringing these instruments to their present state of perfection; but it is hardly less true that, in the estimation of the public, the science and art involved are ignored, and the watchmaker's shop excites no interest except that occasioned by the purely ornamental nature of the objects exhibited.

Let me give you, at the outset, an illustration of the extraordinary degree of accuracy that is now attained in machines for the measurement of time; and I will select one that can hardly fail to bring this point home to you. The chemical balance is a simple scientific instrument that is specially free from the influence of interfering causes, and yet, in its highest perfection, it cannot be made to indicate less than one-millionth of the load in either pan. Thus, with 1,000 grains in each pan, the balance may indicate  $\frac{1}{1,000,000}$ th grain. It is no uncommon occurrence to meet with a chronometer that does not vary more than  $\frac{1}{1,000,000}$ th second per 24 hours, or nearly two-millionths of the time measured out, notwithstanding that it is comparatively a complex mechanism, subject to many sources of irregularity, such as variation of temperature, motive force, consistency of oil, &c.

But, although the construction of timekeepers has been brought to such a degree of perfection, and is a question that concerns us all, it has failed to receive the attention it deserves. Its literature in this country is, with one or two notable exceptions, valueless, or nearly so, as a means of interesting non-technical readers. The art has thus been neglected by amateurs, while the trade has for many years been in a somewhat desponding state. But this has not been the case in other countries. France is remarkably rich in horological literature; and the Swiss, regarding watchmaking as a staple industry of their country, have never failed to do all in their power to promote its interests.

We cannot but feel, therefore, that a special consideration of the subject of watchmaking would at this time be particularly opportune in England, and if these three lectures are instrumental in leading to any discussion of the present

condition and future prospects of this most interesting art among us, I shall feel that my labours have been well repaid. While endeavouring to do justice to the exceptional interest which my subject possesses for amateurs and those who are not concerned with it as a commercial pursuit, I shall endeavour, by a comparison of the methods adopted at the several centres of this industry, to ascertain whether changes could, with advantage, be introduced into our system of manufacture, in order to enable England not only to render more secure the position she has so long held, of producing timekeepers unsurpassed by those of any other country, but also to do more than she at present does in the cheaper markets. For it appears that, while the annual total productions of all the other centres of the watch manufacture, in France, Switzerland, Germany, and America, have shown a marked advance, that of England has at best remained stationary—a fact which the statistics of the English watch and clock trades, given in the next lecture, will bring into prominence.

With the exception of turret, regulator, and chime clocks, England has already quite lost the trade in this branch of horology; it retains, however, the first place in the production of high-class watches, and, as regards chronometers, we may still claim to be the foremost producers, for not only are our own naval and mercantile marine supplied, but also to a very great extent those of most other countries.

From the following table, which has been compiled by M. Saunier, it will be seen that in money value England contributes about one-fifteenth of the total production of the world, including all branches of horology, while nine-fifteenths of this total amount is manufactured in France and Switzerland.

#### ANNUAL PRODUCTION OF HOROLOGICAL INSTRUMENTS IN THE WORLD.

<i>France.</i> —Turret clocks, timepieces, watches, and chronometers..		£2,620,000
<i>Switzerland.</i> —Watches .....	2,400,000	
<i>America.</i> —Watches and clocks .....	1,280,000	
<i>Germany.</i> —Clocks .....	1,000,000	
<i>England.</i> —Chronometers, watches ....	640,000	
<i>Austria.</i> —Clocks .....	400,000	

Such a table cannot be more than the very roughest approximation, on account of the difficulty there is in getting reliable statistics, but, if we accept its conclusions, showing as they do that the value of our produce is small in comparison with that of other countries, we must remember that much of the English work bears a very high stamp, and, even if the fabrication of ordinary watches and timepieces is at the present day in great part appropriated by other countries, we yet have a branch of the trade peculiarly our own which well deserves encouragement; and, at the same time, let us not despair of recovering some of the lost ground in cheaper markets. A capacity for seeing the good as well as the bad points in the productions of our neighbours, and a greater willingness to modify our established practice as experience dictates, would greatly help to redeem the character of the cheaper class of English watch.

It may be said that such questions are too technical to interest a general audience, and that they should be discussed and settled by those

commercially interested in the art. But altogether the case, and for several reasons watchmaker's art has too long been in care of itself, the public regarding it as into which they could not enter, and which possess little or no interest for them. And yet they often take care to dictate more or less unreasonable, because they are not familiar with the advance of the art; and the wearing very thin and very small watches for long periods without the slightest regret that such conditions are fatal to the keeping. The absence of literature is, to some extent, responsible for these things, but, neglected though it has been, it is now beginning to hope to be able to show, in the coming lectures, that our English watch trade is well worthy of attention on account of what has been done in the past, also urging it with a view to improving its position in the future. And in order that I might make the subject to some extent from actual I have visited several centres of the watch industry in this country, Coventry, Prescot, and Birmingham, being acquainted already with the work in London; and I would take this early opportunity of thanking very sincerely all those members of the trade who have enabled me, often at considerable inconvenience to themselves, to see in numerous operations that are involved in the production of a watch. I shall more particularly specify those to whom I am thus indebted in the second lecture, when explaining the manufacture.

Before proceeding to consider briefly the stages through which timekeepers pass from arriving at their present state of perfection, I may be well to ask, What is time? It is more easily asked than answered, and cannot be pictured to ourselves what time is. We can only appreciate an interval of time between two events, and it is sufficient evidence to show that the interval between two events, A and B, is not less than the period between events, C and D, we say that the intervals are equal. But such a statement is only a supposition that the evidence is sufficient to show that the division of time must ultimately rest on a position, doubtless highly probable, but certain, since we are not so organised as to be able to test it, that the period of recognition of a definite phenomenon is invariable.

It is, then, well to remember that our arrangements for the measurement of time can be justified, they do rest on a basis which is entirely beyond our power to prove or disprove. If the above assumption, however, be granted, we at once have a method of testing the time-keeping properties of clocks and watches, and no further supposition made.

From this point of view, a watch is not an instrument for causing an interval of time to pass at a uniform rate, but rather an arrangement for conveniently counting up equal short intervals of time, i.e., the periods represented by the balance or pendulum.

It should be observed that the period of time that is taken by

nt varies according to circumstances, unit of weight is a grain, ounce, pound, cording to the value or bulk of the whose weight an expression is required.

take thousands of years as a unit, s comparable with the periods assumed lapsed between successive important the formation of the earth's crust.

on the other hand, often deal with e fractions of a second. Thus, light is ravel at a rate of about 196,000 miles , and yet it was found possible to us velocity from so short a period as onths of a second, the time required to a distance of not more than six miles. ary transactions of life, a minute, hour, n week, may be considered as a unit, to circumstances; and it is a marked io of modern life that the tendency is e adoption of the shorter intervals as

knows that a day is the interval that een two successive risings or settings and an hour is understood to be 1-24th ival, while the minute and second are 1-60th and 1-60th of an hour. But it is e pointing out that the measurement of so simple as would appear from such a

Let it be granted that each revolution is performed in the same interval of y is defined as the period that elapses e departure of any meridian from a dy and its succeeding return to it, as the aid of a transit instrument; and, were the sole moving body in the ransit observations made on all the dies would prove these intervals to be the same. The stars may, for all rposes, be regarded as stationary; and earth's revolutions be determined by s made on any given star, all days will

length; the sun, moon, and planets er, also in continual motion, with ot only different from each other, but each particular body. The length of a s determined by any of these bodies, usarily be a variable quantity. To ase of a solar day. Our earth m west to east, performing each in a constant period; but its nd the sun, that is, in the ecliptic, at the sun appears to be revolvt, also from west to east, but with a elocity; any given point on the earth's to perform more than a complete before its meridian can, so to speak, e sun, and the solar day will be longer eriod occupied by a revolution of the corresponding amount. The case is, aking, analogous to that of two suc- idences of the hour and minute hands

Assume that the hour hand indicates d the minute hand a point on the earth's l that they are together at noon. The d at once advances on the hour hand, remained stationary, would again coin- in 60 minutes; but, in the meanwhile, und has advanced through a space of , and thus, to an observer supposed to *extremity of the minute hand, the*

"solar day" would be rather more than 65 minutes, although a complete revolution was per- formed in 60 minutes. Owing to various causes, however, into which we cannot now enter, the difference in the case of the sun is a variable quantity; it can be determined by the aid of tables of the equation of time.

The day of 24 hours is the mean or average of all the apparent solar days in a year. It does not represent the time occupied by the earth in per- forming a revolution on its axis, a period which, observed from a distant fixed star, would be found to be 23 h. 56 min. 4.09 sec. of mean solar time; and, although an arbitrary division of time, it has important advantages, because clocks cannot be made conveniently to go with the sun, but can be arranged to go uniformly. It is thus seen that we have three kinds of day to measure. A true or apparent solar day is the period between two successive coincidences of the sun with the meridian of any given place. It is the inter- val between two successive noons on a sundial, but cannot be recorded by an ordinary clock since the days are unequal. A mean solar or civil day is the average of all the true solar days in a year, and corresponds to Greenwich mean time, or what is often termed "railway" time. Lastly, a sidereal day is the period occupied by each revolution of the earth, or, as already explained, 23 h. 56 min. 4.09 sec. of mean solar time. All sidereal days are of equal length, and thus, if a watch or clock be set to gain 3 min. 55.91 sec. per day on Greenwich mean time, it will indicate sidereal time, assuming, of course, that it be in the first instance set with a standard sidereal clock.

Although my principal object is to consider the systems of manufacture of watches, there are other points of view from which the measurement of time possesses much interest, not the least impor- tant of these being the historical. I propose, there- fore, at the outset, to briefly enumerate the several stages time measurers have passed through, especially referring to those of a portable character. The natural divisions of time, which cannot have escaped observation in the remotest antiquity, are such as the rising and setting of the sun, and the phases of the moon. But there is very great un- certainty as to the earliest means in use for the measurement of time. Certain French writers assert that the obelisks were originally set up as a means of indicating the time by the sun's shadow, a view which seems to derive some sup- port from the term "finger of the sun," applied to them by the Egyptian priests. On the other hand, their position at the entrances to temples, &c., seem to render this view doubtful. The first obelisk is said to have been set up B.C. 1485.

The sundial may have been the result of a gradual improvement in some such form of time indicator, but the evidence as to the precise date of its invention is far from definite. The text in the Book of Kings, referring to the "dial of Ahaz," who reigned about 730 B.C., cannot be accepted as conclusive evidence of their use at that period, as the word translated "dial," is the same as is rendered "degrees," in the same verse. Some authorities assign the discovery to Anaximander (B.C. 610—547), the reputed inventor of maps; but, after all, the question turns on the definition of a sundial, for the Egyptian obelisks would

suffice to determine mid-day and, in a sense, to subdivide the day. The essential feature of a sundial is a style fixed parallel to the axis of the earth; its inclination will, therefore, gradually increase as we move from the equator, where it lies horizontal, to the poles, where it is vertical. The shadow of this style is cast on to a graduated circle.

The first time-measurer, whose action did not depend on astronomical phenomena, was the clepsydra or water-clock, an instrument which, probably existing in a simple form much earlier, was brought to a high state of development by Ctesibius, about B.C. 250. In its primary form it doubtless consisted of two vessels, one of which, containing water, was fixed above the other, and into this latter the liquid gradually escaped, indicating the time by the rise of its level. It is curious to note that the Brahmans of the present day are stated to employ a similar system for the measurement of periods of time. A copper vessel perforated with a small hole is floated on water, and immediately on its becoming full the attendant empties it, and strikes the hour of the day or night. But the problem of adapting the clepsydra to indicate the time was one of considerable complexity. For it must be remembered that the day and night were each divided into twelve hours, these hours therefore differed between themselves, and varied from day to day. The ingenuity displayed in the construction of these machines is truly wonderful; some of them automatically adjusted for this variation in the day's length, while in others the adjustment required to be made by hand. Anyone interested in their construction will find several forms illustrated and described in Rees's "Cyclopædia," article "Clepsydra."

If we may credit the accounts that have been handed down to us, some remarkably complicated mechanisms, based on the water-clock, and giving all the movements of the heavenly bodies, signs of the zodiac, &c., as well as indicating the time, were invented before the next great advance in horology, the introduction of a weight motor ten or twelve centuries later. I will only add that the principle of the elepsydra is still of very great value to the physical experimentalist where brief and irregular intervals of time require to be measured with accuracy. With a properly arranged apparatus, it is only necessary for him, by depressing a handle, to start the flow of water, and to release the handle immediately on the completion of the observation. The weight of water thus allowed to escape affords a means of measuring the time elapsed.

The sand-glass, or clepsammium, was probably discovered subsequently to the water-clock, and authorities differ very much as to the date of its first introduction. It is, perhaps, safe to assume that this was at some period during the first three centuries of the Christian era.

Water appears to have afforded the sole motive power for clocks till towards the close of the tenth century, when the celebrated Pope Sylvester II. is generally credited with having constructed a clock for Magdeburg, which was driven by a weight. Professor Hamberger, however, in a paper read in the year 1758, and published by Beckmann,\* doubts his title to the discovery, pointing

out that no mention is made in the original by Dithmar, of either wheels or weight considers the invention to have more consisted of a sundial, and substitutes Abbot of Hirschau, in the eleventh century, having introduced a timekeeper which was events, neither a sundial nor a water-clock; subsequent part of his paper he suggests Saracens, "to whom we are indebted for the mathematical sciences," were in all probability inventors of clocks moved by wheels and

But the references to horology in the of this early period are exceedingly meagre we have no precise evidence of the use of controlled by what is now termed an escapement until the 14th century, when the verge, or escapement, one form of which is shown

FIG. 1.

came into use. The mode of action of it explained when we come to consider it generally.

It is impossible to believe that no progress made during these four hundred years, single inventor is entitled to the entire discovery of the new clocks. No definitely say who it was that first introduced them; for about the same time, early in the thirteenth century, there lived, in England, John Wallingford, Abbot of St. Albans (which is a curious coincidence, is now being restored at the expense of Sir E. Beckett, one of the prominent living horologists); in Italy, John Dondi, doctor and astronomer of Padua; in Germany, Henry de Vic, all of whom were famous as clockmakers.

The next important horological advance to have been made by Peter Hele, a clockmaker of Nuremberg, who, in the early part of the fifteenth century, succeeded in overcoming the difficulty in the way of a portable timepiece, the fact that the motive power was obtained from a descending weight; this he replaced by a steel spring. In the early watches, which retained the name of "Nuremberg eggs," the escapement, similar to that already shown in Fig. 1, was employed. The balance, in the early watches, was only a straight bar with weights at its ends, represented in Fig. 2, was not provided with a balance-spring, for the verge escapement

\* "History of Inventions," vol. 1., p. 340. 4th Edition. 1848.

others in being capable of performing  
ons as a controller of the mechanism,  
ry imperfectly, without this addition.

first use in a watch in place of the stackfreed, are  
alike unknown; but a very remarkable clock in  
the possession of the Society of Antiquaries,<sup>\*</sup>

FIG. 3.

early watches, a peculiar device, known  
*stackfreed*, seems to have been first used for  
a greater degree of uniformity in the  
force. No description of this arrangement  
reached down to us, but I have made this  
Fig. 3), based on a brief account given by  
Morgan, Esq.\* It will at least afford a  
notion as to the manner in which the stack-  
freed have worked. As a spring is gradually  
unwound in a barrel, the force tending to cause  
rotation increases, and the watch will gain. The  
end of the mainspring being fixed, the inner  
end is attached to an arbor that carries the wheel A,  
which engages with the wheel B, of 24  
teeth (space D) of this wheel being left uncut  
to stop. As the arbor of A makes three  
rotations in a day, B will turn once in  
a period. On its axis is fixed a cam of  
the form as C, against which a powerful  
spring presses. Assume that, in unwinding, A  
moves in the direction of the hands of a watch.  
The force opposed by the spring pressing on C to  
rotate B will gradually diminish as it rotates.  
When the spring is about half down, a period is  
reaching during which the opposing force remains  
nearly constant, and afterwards, while pressing against  
the convex face of the cam, it supplements the  
force of the mainspring to a gradually increasing  
degree, thus the tendency is to secure an approxi-  
mately uniform motive force.

the center of the fusee, and the date of its

seems to afford authentic evidence of its having  
been employed for clocks as early as 1525. The  
timepiece in question, bears the name of Jacob  
Zech, of Prague.

It is worthy of note that, up to this period,  
timekeepers appear to have been employed for civil  
purposes and in monasteries, not as astronomical  
instruments; but it now began to be felt that  
they could render important aid in that branch of  
science. The credit of having first used a clock  
in the observatory, is claimed for Walther, of  
Nuremberg, towards the end of the fifteenth  
century; and in 1530, very shortly before the  
announcement of Hele's discovery, G. Frisius,  
a Dutch astronomer, suggested, that longitude  
might be determined at sea by the aid of portable  
clocks, thus opening up a question which, more  
than any other, has stimulated the progress of  
horology.

Galileo, about 1639, made the next great  
advance when he published his treatise on the  
properties of the pendulum, discovered, probably,  
towards the close of the previous century. But he  
did not actually apply it to a clock, although he  
is asserted to have dictated to his son Vincent,  
after being struck with blindness, the description  
of a pendulum clock; the honour of this applica-  
tion is claimed by Huyghens, V. Galileo, and  
Hooke.

I cannot pretend to discuss their respective  
claims; suffice it to say that to Huyghens, whose

\* "Archæologia" (1849), vol. xxxiii., p. 295.

\* "Archæologia" (1849), vol. xxxiii., p. 8.

profound knowledge and ingenuity raised horology from being a purely empirical art into the position of a science, is almost universally awarded the credit of this invention. Although the substitution of the pendulum for the old form of balance, had immeasurably improved the timekeeping properties of the clock, Huyghens, finding that the vibrations of a pendulum are not rigorously isochronal, or performed in equal times when of varying extent, endeavoured by the aid of geometry to further increase its accuracy, and was thus led to the discovery that if a pendulum be caused to perform a cycloidal instead of a circular path the vibrations will always occupy equal intervals of time. This profound research into the properties of the pendulum was mainly prompted by an ambition to employ the clock for determining longitudes at sea, in accordance with the suggestion of Friarius, nearly a century and a half previously; and Fig. 4

FIG. 4.

is very interesting as representing a form of clock, supported in gimbals, and maintained steady by a heavy weight below, which Huyghens proposed for that purpose. Robert Hooke, however, assures us that Lord Kincardine had, a few years previously, experimented on a similar form of clock; and the very first number of the "Philosophical Transactions" of the Royal Society, published in March, 1665, contains a note, describing the successful employment of these "pendulum watches" by Major Holmes, on a voyage from Guinea to the "Isle of Fuego."

Huyghens was led, by his investigations, to the discovery of a fact of infinite importance in the exact measurement of time, the fact that when a pendulum oscillates through very short arcs, their periods are isochronal within the limits of observation. The verge escapement, however, the only one in use at the time, required a vibration of considerable extent, so that the great geometer was precluded from taking advantage of his discovery, which follows directly from his law of the cycloidal path, since, for short arcs, the circular and cycloidal paths are practically coincident.

It was about this time (1660) that the discovery of the balance-spring, by which portable timekeepers indicating the time with any degree of accuracy were, for the first time, rendered possible, was announced by Dr. Robert Hooke; and his invention was very soon claimed by Huyghens and Hauteville. Although authorities generally con-

cur in admitting the Englishman's title to have first applied a spring to the balance, Huyghens seems to have first employed, in 1674, a spiral spring, such as is in universal use at the present day. This well-known arrangement is shown in Fig. 5, from which it will be seen that the

FIG. 5.

end of the spring is attached to the balance. B is a stud fixed in the balance-cock, in which the outer end is fastened; and, at P, the spring passes between two pins in the index, and is attached to the balance-cock, T.

The adaptation of the pendulum to a watch, and the application of a steel spring to the balance, gave a stimulus towards some improvement of the foliot or verge escapement, the only one in use either in clocks or watches. So long as it continued in use, Huyghens was compelled to secure equal vibrations in clocks, since relatively long or short vibrations were essential. This he did by applying the cycloidal cheeks to the upper end of the pendulum rod, in the manner shown in Fig. 6.

FIG. 6.

two shaded pieces are in the form of a cycloid, the pendulum is suspended by two parallel threads, which alternately wrap over these

oved that the path of the bob will also. In 1680, Clement, a London clock-maker, made a great step in advance by introducing an anchor escapement, with which the pendulum, therefore more nearly isochronal motion, were possible. The form of the escapement was changed to that shown in Fig. 7, so as

FIG. 7.

dead-beat instead of a recoil escapement, years later, by G. Graham, a man no more than any other Englishman in the art of horology. His more important inventions, the cylinder and dead-beat escapements, and the mercurial pendulum, steamed at the present day; the well-known pendulum was also first suggested, although carried out by Harrison. It is reasonable to assume that his invention in the anchor escapement led to the variations, since the rates of clocks had only been sufficiently good to render useful by changes of temperature of any other escapements and other methods of motion have of course been invented since his day, and the details of workmanship improved, but he is unquestionably due the credit of having first made an isochronal regulator possible, and the unimportance of the few changes during the 160 years that have rendered indisputable testimony to this fact. Improvements in stationary clocks were followed by important advances in timekeepers, with a view to the measurement of longitude at sea; an operation which depends on the exact coinci-

dence of two timekeepers that are separated from one another. This is obviously a problem possessing the highest commercial importance, and the labours devoted to the perfection of marine chronometers have, at the same time, given us all the greatest improvements in pocket watches. The interest excited by the question can hardly be appreciated at the present day, when every ship carries one or more chronometers as a matter of course; all the maritime Governments offered rewards for its solution, and our own Parliament, on the recommendation of a committee of which the immortal Newton was a member, voted in 1714 a sum of £20,000 to the inventor of a marine timepiece that should not vary more than two minutes in 42 days, thus giving the longitude to within half a degree at the end of that period.

Henry Sully, an Englishman living in France, was one of the first to take the problem seriously in hand, and in 1723 he completed a clock for use at sea. It can hardly be taken as a proof of any radical advance in the art, and, considering how highly esteemed its inventor was as a horologist, we may be surprised that he should have designed such an instrument. Moinet assigns as a reason for giving a somewhat detailed description, that it will "serve as an illustration of the errors into which a man of ability and some experience may fall." A heavy circular balance is supported by a horizontal axis on anti-friction bearings. This axis also carries a radial pair of curved cheeks, and an index, the whole being in equipoise. The escapement by which the impulse is communicated partakes of both the verge and lever forms. A cord attached to the balance-staff, and passing alternately over the two cheeks, is connected with a circular arc forming part of a horizontal lever, also on anti-friction bearings, with which this arc is concentric. While the lever is raised by the action of the escapement, its descent gives an impulse to the balance; the action of the weighted lever, then, corresponds to that of a balance-spring. It is useless to point out the objections to such an arrangement, which, after all, only involves the use of a pendulum in disguise; the friction throughout the escapement was excessive, and the instrument was not independent of position or latitude. He seems to have gone out of his way to avoid using the balance-spring, then well known, and failed to see how essential it was to entirely change the escapement itself. This most important investigation was taken in hand by his immediate successors, Harrison and P. Le Roy, the inventors of a special remontoire and of detached escapements respectively, and the former secured the award of the English Government in 1767. In a remontoire escapement the motive force, instead of acting directly on the balance, is employed to raise a weight or spring which, in turn, impels the balance, the object in view being to secure a strictly uniform motive force. But horologists now generally admit that in a watch or chronometer such a precaution is entirely unnecessary, and it was Le Roy's great discovery, first announced in 1748, that led the way to the final solution of the problem, the chronometer escapement of the present day. I shall presently have occasion to refer to the principle of detachment which he introduced, and would here only explain that it consists in releas-

ing the balance from its connection with the other parts of the escapement during the greater part of its motion.

Portable timekeepers had now reached such a degree of perfection that their rates were appreciably affected not only by variations of temperature, but also by the want of isochronism when the arcs of vibration were of varying extent. Harrison's elegant mode of counteracting the first of these interfering causes by a bimetallic strip applied in various ways was only equalled by that most beautiful discovery of Le Roy's—the isochronal balance-spring; they were both essential to the perfecting of the marine chronometer, and it appears we can no more dispense with the practical suggestions of the one inventor, than with the more theoretical discovery of the other.

Many great horologists have lived since the days of these men, but they have worked mainly on the lines indicated by them. It would be travelling beyond the limits of a general historical sketch to refer to the special work of Arnold, Karnshaw, Berthoud, Breguet, and others, in the endeavour to improve the marine chronometer. We are mainly concerned with the pocket watch, and it is noticeable that, prior to 1760, attention seems to have been directed towards increasing the complexity rather than the timekeeping properties of the instrument. Thus the invention of repeaters took place immediately after that of the balance-spring, namely in 1676 and Johannes Coccius states that Hele even made a "striking watch" early in the sixteenth century; indeed, throughout that century, striking, alarm, and calendar watches seem to have been not uncommon.

The verge or "pallet" escapement was the only one in use for watches until 1700, when Graham perfected his cylinder escapement, based on a suggestion of his master, Tompion. This form, though unsuited to the chronometer, has been used more than any other in watches, for reasons that will be evident when we consider it more in detail. It cannot be doubted, that many efforts were made to adapt to watches the dead-beat escapement, which had proved to be of so much value in clocks, but an important difficulty lay in the fact, that, while this form of escapement requires only a short arc of oscillation of the pallets, the regularity in the rate of a balance is materially impaired if the extent of its arc of vibration is reduced. It was essential then to so co-ordinate the balance and pallets, that these two conditions were satisfied. The Abbé Hautefeuille invented an escapement as early as 1722, which satisfied them, but fresh sources of error were introduced. It is known as the rack lever, and shown in Fig. 8. The balance, *c* *D*, and escape-wheel, *A*, are concentric, but on independent axes. On the balance-staff is a pinion, *F*, which engages with the segmental rack, *X*, at one end of a poised lever, *EG*; to this are fixed the pallets, *B*, as in the modern lever watch. Indeed, this is the forerunner of our modern escapement, from which, however, it differs in one essential particular. The balance is never liberated from the lever. This very important modification was introduced about 50 years subsequently by Thomas Mudge, a well-known English maker, in a watch he made for Queen Charlotte. His own account of the invention shows that his escapement closely

resembled the "right-line lever" very different from that in Geneva watches; the valve

FIG. 8.\*

discovery of Mudge's consists in the fact that during the greater part of its vibration the is detached and free to move out of contact with other portion of the mechanism.

One other radical change in the pocket remains to be mentioned. A few years after effected this improvement (1766), the *c* Lépine, associated with Voltaire in the factory at Ferney, introduced his important modifications in the arrangement of a watch—which have been maintained until the present on the Continent, in all but the cheaper factories. He suppressed the fusee and a pillar-plate, and one pivot-hole of the barrel one plate only being used, and the top pivots by separate cocks. The fusee was thus removed from the barrel, which, being provided with teeth, communicated its motion direct to the main axis, and became known as the "going watch." These changes were made clear by the large diagram and a model, showing all of a watch, kindly lent by Sir John Benn.

We have now very briefly traced the history of horology from the earliest times to the present day. The originators of the clocks, chronometer watches in use at the present day. While the escapement used for most of clocks, Graham's dead-beat, was invented as 1700, the commencement of the present found the modern lever and chronometer movements already the subject of investigation patient experimental determination of suitable proportions, and of various details of construction, of these as well as of the escapement, has mainly occupied horologists that period. The principal errors to which is subject had been overcome by Graham Harrison and many who succeeded him, and to avoid irregularities in the rate, owing of isochronism, by a constant force or verge escapement, relying on this absolute uniformity in the motive power giving an action of invariable extent; Le Roy's investigation into the action of the balance proved, however, that the true solution problem lay in the fact that there is a

\* This block, taken from Neithrop's "Dictionnaire de l'Horlogerie," is kindly lent by Messrs. Benn, 5, 6, and 7, St. Martin's Lane, London, and Messrs. Lockwood and Co., Ltd., London.

given spring, providing it is well made, which is vibrations of varying extent to be period in equal times, just as, with the pendulum, is a path, the cycloid, that alone secures it isochronism. That other principal source of irregularity in clocks—variation of temperature sets portable timekeepers to a still greater extent, and although more inventive power has expended on the question of compensation on any other, it is still but partially solved; and, it is well worthy of note, as illustrating at the remarkable progress made by the earlier horologists and the very slight advance made in their day, that the compensation balance, as in Fig. 9, which is now often used in

FIG. 9.

chronometers and always used in the best ones, differs in no respect from those employed by Arnold and Earnshaw at the latter end of the eighteenth and beginning of the present century. Arnold, as early as 1775, took out a patent for the cylindrical or helical balance-spring used in chronometers, and, nine years after, he invented his flat balance-spring with overcoil, which is now esteemed the best for watches. (To be Continued.)

#### DOMESTIC ECONOMY CONGRESS.

(Report continued from p. 661.)

A meeting of Thursday, 23rd June, was held at Royal Albert Hall, at 11 a.m.; Mrs. DACRE CRIVEN in the chair, and Dr. MANN, F.R.C.S., M.D.

#### ON C.—THE DWELLING: WARMING, CLEANING, AND VENTILATION.

Dr. MANN called attention to the fact that the meeting presided over by a lady, the Assessor simply acting as assistant, and desired that all remarks, therefore, should be addressed to her.

Mrs. Dacre Craven read a paper on "Warming, Lighting, and Ventilation of Schools and Dwellings in Small and Large Towns, from a Nurse's Point of View."

Mrs. Dacre Craven, in answer to the question how they could best acquire the practical knowledge required, said that nurses for the sick poor were sent at Bloomsbury-square, and they might teach in their parishes.

Lady suggested that the St. John's Ambulance Association might be made useful for this purpose.

Henry Cole asked what age Mrs. Dacre Craven

would recommend should be fixed as the earliest for the teaching she recommended? He desired to emphasise the point that a commencement could not be made too early, and should certainly be made in the infant school. With respect to the defects in good houses as well as bad, both in London and the country, even in Birmingham, where the people lived under an efficient and watchful municipal despotism, he found in a house he was going to occupy there a stream of sewer gas flowing into the cellar, and that the water was not potable. He found all the defects that could well exist in a house, and had saved his health by taking care to get them remedied at once by making complaint in the proper quarters.

Mrs. Dacre Craven said that in old-fashioned houses windows were not constructed to open at the top. In his own house in London, built a hundred years ago, not one of the windows had been so made, and he had had to remedy that defect. Many people really did not seem to understand that opening windows in that way was a necessity for letting out foul air, and often their only chance of getting proper ventilation was when a window happened to be broken. Most simple means could be used for the purpose if people would only adopt them, as it was an easy thing to leave a window open for a small space at the top and to hold it up at the bottom, even in the absence of proper sashes, by the insertion of a piece of stick.

Mrs. Talbot said she had found the advantage of recommending, in latticed windows of small houses, the knocking out one or two of the small lattice panes.

Sir Henry Cole said there was a general and profound ignorance on the subject of ventilation, and even where in schools the necessary arrangements were made for obtaining it, the students would manage to get rid of them if they possibly could. Women, he thought, would be much better advocates and inspectors in these matters among poor people than men.

Miss Kewrick said there was no difficulty at all in making children, in the 4th, 5th, and 6th standards, thoroughly understand what was best to be done, in cases of sickness, scarlet fever, changing linen, and so on. They gave their mothers the benefit of the instruction they had received, and by following what their children were able to tell them the parents were often successful in preventing the spread of disease.

Frau Morgenstein offered a few remarks in German, giving her experience of her schools of cookery in Berlin, where 10,000 workpeople were daily fed. She had also interested herself in taking females direct from prison, and by educating them in these matters, enabling them to become respectable members of society.

Mrs. Dacre Craven said Frau Morgenstein's remarks would have more application in the cookery section.

Dr. MANN said that the great objection to open windows on the score of draught, might be obviated by the use of copper wire gauze, hooks, and a few simple appliances.

Mrs. Dacre Craven suggested that the foul air from sinks and dust-bins might still enter, and that care must be taken to prevent any danger from that source.

Lady Stuart Hogg thought poor people might find difficulty in providing themselves with the copper gauze and other things recommended.

Dr. MANN said difficulties would soon disappear when people were once made to understand what was required to be done.

Paper by Miss Pilkington, on "The Walton School Laundry," was read by Miss Webb.

Miss Guthrie Wright recapitulated from a small hand-book she had written, directions for washing as given at the Edinburgh School of Domestic Economy.

Sir Henry Cole referred to an order promulgated as long ago as 1857 by Mr. (now Sir R. R. W.) Lingens, Secretary of the Treasury, with regard to the establishment of laundries, and remarked that a miserable decadence had taken place since that time. He was unable to say whether laundries did exist in all the female training colleges, but from some cause or other it was found that where established it was cheaper to give out the washing than that it should be done by the students themselves.

Miss Harriett Martin's paper, "Washing-day in Cottages and Small Dwellings; Some Hints upon the Method of Teaching Washing," was read by Dr. Mann.

Rev. Daere Craven said few houses in London possessed means of obtaining soft water. Teachers would be very willing to instruct girls how to wash by practical demonstration, but proper washhouses should be provided for the purpose, for it would be impossible for much good to be done with a board and a piece of calico; and the schoolmistress of the present day might not care to give practical instruction at the washing-tub. Still, that was the only way in which it could be done properly.

Sir Henry Cole thought the practical teaching might be given in public laundries if established. Such laundries might be organised in connection with the Board schools, and thus utilised for teaching purposes.

Mrs. Talbot considered that any School Board which proposed to take the ratepayers' money for building a laundry would raise a storm of opposition.

Sir Henry Cole was not proposing that that should be done, but that the parochial powers should establish baths and washhouses, and co-operate with the School Board for their use for teaching purposes. He was glad to find that in Bermondsey and some other parishes in London buildings of that description had been erected, and the matter was one which merely required a little organisation.

Miss Guthrie Wright thought that poor children in schools were already over-burdened by teaching, and she thought laundry work should not be added. The difficulty might be solved by the adoption of the continental plan of establishing technical schools, to which girls might go after leaving the elementary schools. Such establishments might work either under the Board or in connection with our public schools, such as that for domestic economy, and there the girls might go through a three or six months' course of teaching in laundry work, dressmaking, or other subjects, which would enable them to find better occupation in after-life. By such a plan as that, the difficulty of teaching children domestic economy in schools would be avoided.

Sir Henry Cole urged that in some respects the Education Code was too exacting upon young children, in subjects which could be of no great use to them in comparison with the teaching of domestic economy subjects. Poetry, algebra, Euclid, French, and German, were some of the matters he alluded to.

Mrs. Talbot said that part of the Code applied to boys, and they could not be taught more than two of those subjects.

Sir Henry Cole said that was two too many. Teaching the children such knowledge was really time and labour thrown away.

Mrs. Talbot added that extra subjects could not be imposed upon the girls until they had been taught domestic economy. It was an advantage to girls and boys alike to learn to understand good cooking.

Sir Henry Cole's argument was, that children were pressed too heavily by the Code, which demanded reading, writing, arithmetic, and grammar from the infants in Standard I. Standard II. required from children of eight, among other matters, notation and numeration up to 100,000, and they had much better

learn something about washing. A child too young to be taught the simple principle economy.

Mrs. Daere Craven said it was a fair question: some of the subjects imposed by the Code left out in favour of others which would be useful.

Mrs. Talbot objected that teachers had enough to do; and said they would never teach washing in addition. Public wash not so eagerly sought after by poor people to be considered; and in her own town, a movement of the kind had been shut up, because would not go out in public and expose their clothing to their neighbours. In London, however, they might accept the alternative to the one room occupied by the family.

Mrs. Daere Craven hoped that in another time the poor would have better houses to live in accommodation.

Mrs. Tullock believed it would be a mistake to wash as part of the school education; a child should be put to stand over a wash-tub, clothing to manipulate, as the age of 13 is early enough for that. It was really not school education at all.

Mrs. Daere Craven remarked that, unpoor children were taken away from school were 13, as they were too useful at home to stay. She had herself learned to wash in Germany, and could testify to the great involved.

Dr. Mann pointed out that to some extent wandering from the question before them, but some easy and simple means might not be teaching children the methods or first principles, if necessary, a little alleviation of it of instruction.

A Lady offered, on behalf of Frau Moore, a paper on the subject of teaching washing.

Mrs. Daere Craven said it would be glad. She had understood that lady's previous remarks rather outside the subject, referring as the manner in which poor people were fed in not to washing, cleaning, and ventilation.

Mr. E. A. Hadley's paper, on "Pure Airiness, the True Basis of Health and Comfort of All," was read by Rev. Daere Craven.

Capt. Douglas Galton, C.B., F.R.S., read "The Maintenance of Pure Air in Dwelling."

Dr. Mann expressed the indebtedness of him to Captain Galton for his valuable paper, for ought to be doubly grateful, as he had a special request.

Mrs. Daere Craven asked whether Captain Galton would recommend the placing of dust and removal of houses for daily removal.

Capt. Galton was in favour of that course covered receptacle were used.

Mrs. Daere Craven said the remuneration by dustmen was an obstacle to their employment; poor people often let their dust and refuse for two or three months. Unless some law passed on the subject of the removal of such nuisance, very little could be done to remedy the state of things in that respect. The airing poor houses was so vitiated by means of the dust-bins, that they could not even obtain by opening their windows.

The meeting then adjourned for a repetition of Buckton's lecture at four o'clock, by Mrs. H.R.H. Princess Christian.

## OF THE SOCIETY OF ARTS.

No. 1,495. Vol. XXIX.

FRIDAY, JULY 15, 1881.

*tions for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## CHAIRMANSHIP OF COUNCIL.

day last, the 11th inst., at their first meeting the Council elected FREDERICK J. BRAMWELL, Inst. C.E., F.R.S., as Chairman for the year. The various committees were also elected.

## EXAMINATIONS, 1881.

of successful Candidates in the Examinations of the present year has been printed, and is now on sale to the Institutions in Union with the Society. Copies will also be sent to the various Local Boards for the successful Candidates.

## PROCEEDINGS OF THE SOCIETY.

## CANTOR LECTURES.

## WATCH MAKING,

By Edward Rigg, M.A.

## LECTURE I.—Continued.

Progressiveness of the last hundred years in watchmaking is in striking contrast to the century which preceded it. In 1680, the watch-spring was but recently invented, and Hully were just born, Huyghens and he still in the prime of life. In 1780, we possessed the dead-beat clock escapement and compensation pendulums, Arnold's sons of the chronometer escapement, balance-springs, compensation balances, and cylinder escapements, in fact, all the lines of our timekeepers of the present we desire to see what progress has been made at that date, we can only seek it in a comparison of the several parts, in production, a more exact workmanship, the scientific knowledge of the laws by which timekeepers are governed. With but few exceptions, the improvements effected in the properties of watches have not resulted from suggestions made with that object in

view, but as a necessary consequence of their resemblance to the chronometer.

One fact, however, in partial explanation of this absence of change, suggests itself. Amongst the earliest application of the mechanical arts was the construction of machines for the measurement of time, and a perusal of the older treatises shows how much ingenuity was devoted to them. Thus it happens that horology was at an early date in a comparatively high state of development, and was not in the same need of radical changes as were most of the other arts of construction. It may further be added that the results attained, as regards timekeeping, have been eminently satisfactory, so that the arguments in favour of a change of system must be based rather on facility and economy of manufacture. These latter, as will be seen from the next lecture, are now forcing themselves on our attention in a manner that they have not hitherto done.

In the preceding historical notice, I have had to refer to many subjects doubtless unfamiliar to some of you, but it did not seem desirable to prolong this branch of the subject by the addition of explanations, that can be better given in the course of the more detailed consideration of the pocket watch, upon which I now propose to enter.

A watch consists essentially of three parts—(1) the driving mechanism; (2) the controlling and regulating mechanism; (3) the indicating mechanism. Fig. 10 (p. 674) represents the mechanism of a full plate watch, or of a marine chronometer, the top plate, together with the escapement, having been removed.

The barrel contains a coiled spring to serve as a motive power, and is connected by a chain with the fusee, which serves to render uniform the force transmitted to the train. From the figure it will be seen that, as the watch is wound up by a key on the fusee axis, the chain is unwound from the barrel and wound on to the fusee, which may be defined as a screw of rapidly diminishing diameter. When the spring is fully wound up, and therefore exerting its maximum force, it acts at the extremity of the shortest power arm, or radius, of the fusee, and this arm gradually increases as the force exerted diminishes. Within the fusee is the maintaining power for keeping the watch in action during the time of winding. The centre wheel, whose pinion is driven by the fusee, carries the minute hand, and engages with an intermediate or third wheel. This drives the fourth wheel, on the axis of which is the seconds hand, and the escape-wheel seen in the middle of the figure is driven by the seconds wheel. The axis of the centre wheel below the plate carries, friction-tight, a pinion of twelve leaves, which, through a wheel and pinion of 48 and 14 respectively, drives a wheel of 42 teeth concentric with itself. The relative rates of these are as 1 is to 12, so that the hour hand travels 1-12th as fast as the minute hand.

The maintaining power seems to have been first introduced by Harrison, in 1736. Fig. 11 (p. 674), although not strictly accurate, will serve to explain the principle on which it acts. The mainspring causes the fusee to rotate in the direction of the hands of the watch, or towards the right. It will be evident, then, that, if the fusee and its wheel were solid, the pressure of the hand in winding, which turns in the opposite direction, would neutralise this motive

FIG. 10.

force, and the watch would stop. Such an inconvenience is prevented by the maintaining power. The brass ratchet wheel in the centre is rigidly fixed to the under side of the fusee; side by side with it, and loose on the same axis, rotates a steel wheel provided with very fine ratchet teeth, cut in the opposite direction to those of the brass ratchet wheel, and carrying two clicks held by springs against this latter wheel. A detent fixed to the plate engages with the ratchet teeth of the steel wheel, and the brass fusee wheel below, which is not represented in this figure, but will be noticed in Fig. 10, communicates motion to the train. A recess in this wheel contains a flat circular spring, indicated by the shaded portion of Fig. 11, one end of which is attached to the steel wheel, and the other to the brass wheel.

FIG. 11.

Now, assume the mainspring to be wound up. The fusee, with the brass central ratchet attached, tends to rotate to the right, and, through the clicks, communicates the impulse to the steel wheel; this impels the fusee wheel, at the same time maintaining the circular spring compressed. While the watch is going, then, the teeth of the steel ratchet pass freely under the detent.

But consider what occurs when the fusee in the opposite direction, during the act of winding. The brass ratchet passes under the click; the steel one is locked by the detent. The spring, therefore, maintains its constrained action until the end attached to the steel ratchet becomes stationary: its elastic force is expended in returning the impulse on the fusee wheel; action will be maintained for a period proportional to the extent to which it has been compressed.

Reference has already been made to the difference in which the ordinary Swiss watch differs from that of English make. I would only here mention the suppression of the fusee, whereby the maintaining power is rendered unnecessary. The barrel is provided with teeth, which mesh directly with the pinion on the axis of the wheel, and, in winding, the inner end of the spring is coiled on to an arbor in the center of the barrel; the barrel, therefore, is constrained to revolve in the same direction as by the fusee during its uncoiling. Hence there is, in the ordinary watch, a continual movement of advance of the train, whereas, when a fusee is used, one end of the spring always remains stationary, and it uncoils about the same mean position.

This distinction causes the first to be called a going barrel, and it is gradually coming into more general use, in watches other than those controlled by the cylinder escapement. The points put forward for and against each form are very numerous, and I shall press no more specially to the question, as the main distinction between the ordinary English and the continental or American watches, when regarded as the essential point on which the two systems differ.

The bearings of the question as to the suppression of the fusee is debatable; it can, however, be better appreciated when the elements commonly used in watches are compared.

ined, as the degree of uniformity required in motive power will necessarily depend on power of the escapement to neutralise its gularities, a power which varies considerably. In escapement, it will be understood, is an diance adapted to the end of a train of wheels order to prevent a too rapid motion, and at the e time to regulate the expenditure of the motive e in such a manner that it is allowed to exhaust f with the requisite slowness and uniformity. variety among escapements is very great; y are suitable for stationary timekeepers, e being quite unfitted for such as are con- tly moved about; some are adapted to the movement of a pendulum, but cannot be oyed without modification with a balance. e ordinarily met with in watches, and which e I shall briefly consider, are five in number, verge, cylinder, duplex, lever, and chronometer, tent escapements. Let us take them in the e here given.

e verge escapement was the first employed mekeepers, having been invented sometime een 1000 and 1400 A.D. It has been assigned ohn Megestein, a clockmaker of Cologne, in ourteenth century, and was the only escape- known up to the middle of the seventeenth ury. An early form is shown in Fig. 1, on 666, from which it will be seen that a vertical suspended at its upper end and terminating in rot, carries two pallets that engage with a n wheel having ratchet teeth, and to the r end of the rod two horizontal arms are , that support equal weights. The pallets are eed at an angle of about  $100^\circ$  to each other, it will be seen that if a motion of rotation is 1 to the wheel, its teeth will alternately ge with the pallets, and impart an oscillatory on to the system. By moving the weights rds or from the centre, the period of this ation can be varied, and the rate of motion of rain of wheels thus regulated. If a balance fixed weight be substituted for this folliot, own in Fig. 2, on page 667, and the whole orted between two pivots, it will be seen such an escapement is portable, and, further, eases the property of continuing to go, even gh unprovided with a balance-spring, as the case until the seventeenth century. ks to the kindness of Dr. Longton, of South- I have here such a watch. It bears the name

of David Lestourgeon, of Rouen, and possesses special interest, both on account of its being unpro- vided with a balance-spring, and owing to the fact that a catgut band is employed in place of the well-known chain on the fusee. Its date is probably about 1640. All its parts appear to be original, and the watch is still in going order.

The principle of the verge escapement is met with in Sully's marine clock, already described, and elsewhere, and the celebrated French horo- logist, Berthoud, had an extraordinary fond- ness for it. There is no question that very good results have, at times, been secured with the verge, but to obtain them requires all the ability of the most skilful workman, and his time is far better employed on the superior class of escapements. A main objection to it consists in the fact that, the motive force being always applied to the balance, any slight variation in this force causes a change in the rate; hence a very carefully adjusted fusee is essential, and the adjustment must be corrected whenever a new spring is fitted. The working parts are subject to rapid wear, and the use of an escape-wheel, in a plane perpendicular to the plates, renders a thick case necessary.

It is worthy of remark, that the objections to a verge escapement in a watch, do not apply with nearly the same force in a clock; and the common "Comté," Dutch, and other clocks are known to be fair timekeepers. This difference arises from the fact that the arc of vibration is so small; and M. Wagner has proved experimentally that the verge is all the more capable of giving accurate results, as the oscillations are made shorter.\*

To turn to the brief consideration of the cylinder, Geneva, or horizontal escapement. As already stated, it was invented by Graham, in 1700, and, for a reason that will soon appear, it is classed by Saunier as a "frictional rest" escapement. Fig. 12 represents an inverted plan of the escape-wheel teeth and cylinder, and Fig. 13 (p. 676) is an elevation of the entire escapement also inverted. The upper portion of the cylinder carries a brass collet, to which the balance is rivetted, and the cylinder itself is a steel tube, half of which is cut away throughout a portion of its length, and three-quarters through rather less than half of this portion. The wheel is provided with teeth projecting downwards from the plane of the paper in Fig. 12, and terminating in triangular formed heads.

Fig. 12.

successive positions of the cylinder in relation both are indicated in Fig. 12, the wheel being led in the direction from right to left. A, B, coming in contact with the edge (e) of the

cylinder, A, causes it to rotate in the direction opposite to the hands of a watch until the heel of

\* Saunier, "Treatise on Modern Horology," p. 67.

B escapes from the edge, and its point falls against the inside of the cylinder at c. The cylinder and balance continue to rotate through the impulse that has been communicated to them, until they are

FIG. 13.

brought back by the action of the balance-spring. Rotating now in an opposite direction, the tooth is released from the inner surface of the cylinder and gives a fresh impulse against the edge, H, as soon as it reaches the point, F, and when the tooth, A, is released, the next tooth falls against the outside of the cylinder; the balance-spring now brings the whole back again, and a similar series of actions recurs. The reason for the distinctive term, "frictional rest," will now be evident. It refers to the fact that, during the entire period the escape-wheel is at rest, there is friction occurring between the point of a tooth and the inside or outside surface of the cylinder, and this friction, slight though it apparently is, is a most important feature of the horizontal escapement; for if, from any cause, the motive power increases, the pressure of the point of a tooth on the cylinder increases proportionately. The friction therefore increases, and the watch goes slower. There is thus a kind of natural adjustment that more or less exactly makes up for variations in the motive force—indeed, it was observed by Jodin more than a century ago, that if the balance is too large, the watch goes slower with an increase of the motive force, and, conversely, when it is too small, it goes faster. It will thus be seen that this escapement possesses one important advantage over the verge: it does not necessarily involve a uniformity in the motive force.

With a view to diminish the friction and wear of the cylinder, it has been made entirely of ruby, but such a construction is difficult and costly, and the rate obtained is not superior to that with a well-made steel cylinder. I shall not, therefore, stop to further describe it in this hasty sketch of the escapements in ordinary use.

The first idea of the duplex is attributed to Dr. Hooke, who employed a two-balance escapement in the watch he designed, in 1660, for Charles II., a watch that possesses considerable interest as being the first to which a balance-spring was applied. It was, however, materially modified by Dutartre, P. Le Roy, and Tyrer, the latter of whom gave it the form shown in Fig. 14. The escape-wheel is provided with two sets of teeth; a long pointed series, whose office it is to arrest the

movement of the train immediately after locking has been effected by the balance series of triangular teeth projecting upon the flat of the wheel, by which the im-

- A The Duplex Escape Wheel.
- B Steel Pallet with Ruby inserted at D.
- D The Ruby Roller.

FIG. 14.

communicated to the balance. In forms of this escapement, there were two on one and the same axis, but its principle course the same.

The axis which carries the balance and spring is at D. It also carries a small tube of ruby, in which a notch is cut. Above the roller is a steel arm, B, propped by a ruby pallet, C. The axes of the escape-wheel, A, are so pitched that the resting teeth, although being held against the surface of the ruby roller, do not reach the notch in it (in the figure they represent an engraver's mistake, set too far apart). The impulse to the pallet, together with the balance, will continue in a direction opposite to that of the watch, i.e., from right to left; during this motion the resting tooth will remain against the roller. On the balance being brought back by its escape-wheel will remain stationary, and the resting tooth drops into the roller; the spring brings it back a second time, and assume the positions shown in the figure, an impulse is applied. From the above explanation will be seen that the duplex resembles the escapement in having a frictional rest; but friction occurs at a greater distance from the escape-wheel axis, and a less distance from the balance, its effect in reducing the motion of this latter is proportionately less; this friction must have a certain enabling the escapement to maintain its

motive force, as in the one last considered ; the two further resemble one another in possessing a kind of natural compensation for variations of temperature. In both, the points of the balance require to be provided with oil. Now, it is known that in the cold the elastic force of a spring increases, and it has a tendency to alterate the rate. But cold will also increase the viscosity of this oil, and, therefore, the friction, rather, the adhesion ; thus, to some extent, counteracting the accelerating effect of the spring. Though it would be too much to pretend that the two influences always neutralise one another, the effect is sufficient to render a compensation once far less essential than it is in detached

escapements, such as the lever and detent ; indeed, it would be inapplicable, on account of the variability of this adhesion with time.

The duplex is unquestionably a beautiful device, and capable of securing very uniform timekeeping, but accurate workmanship is in the highest degree essential. For this reason, and owing to the fact that it is liable to be disturbed in its action when carried, the duplex is considered less satisfactory than the lever, which, for the same degree of ability on the part of the workman, secures a better rate.

There are many varieties of the lever escapement, but that most frequently made in England, and known as the English lever, is shown in the diagram (Fig. 15). This escapement is by far the best that

FIG. 15.

yet been devised for portable timekeepers, and widely displacing all others, even the cylinder ; already referred to some of its earlier forms. The arrangement adopted by Mudge, in place of the lock and pinion of Hautefeuille (Fig. 8, p. 670), somewhat difficult of construction, and has since been simplified, but the principle remains precisely the same. Indeed, it is worthy of note that in the approved form of the lever escapement, known as the double roller, we have a remarkably exact copy of Mudge's original design.

In the ordinary English lever the balance is pivoted on the axis, A, on which is also a steel disc, carrying a semi-circular ruby pin, e, and a guard-pin in crescent form, as indicated. The impulse is communicated by the escape-wheel teeth to two faces, c and c', of the "pallets," which are attached to a light steel lever, eg. At the extremity of this lever is a notch, into which the ruby-pin enters during its rotation, and a brass pin, indicated by a black dot, and termed the "guard-pin," whose position will be presently evident. Consider the several positions shown in the diagram, and the balance rotating to the hands of a watch. The ruby-pin, e, having just entered the notch, lifts the end of the lever, and releases the tooth from the locking face, a, of the pallet, a c. In traversing

this pallet, the tooth will communicate its impulse to the lever, and the ruby-pin will be impelled forward by the lever side of the notch, until, when the lever rests against the opposite pin, h', it escapes from the notch, and during the remainder of the vibration the balance is entirely detached. The tooth falling against the locking face, a' will maintain the lever stationary, but, in order to avoid any accidental displacement, the guard-pin near the notch, already referred to, is added. This is almost in contact with the roller on the axis, A, so that the lever cannot leave h or h' except when the guard-pin is opposite the crescent in this disc, in other words, when the ruby-pin is receiving its impulse from the notch in the fork. The elasticity of the balance-spring causing the return of the balance with the attached roller, the ruby-pin will again enter the notch, travelling in an opposite direction, and will receive a further impulse from the tooth acting on the pallet, a'.

It is very usual, both here and abroad, to distribute the incline between the teeth and pallets, and some makers have transferred the inclines entirely to the teeth, giving the pallets the form of English escape-wheel teeth. The principle of the escapement, of course, remains the same, whatever form is adopted, and good

results have been obtained from all. It cannot be denied, however, that the pointed teeth are less made than formerly; they possess advantages in that they allow more oil to be retained on the surface of the pallet, and are more easily made. On the other hand, with club teeth the friction is distributed between two points instead of one, the oil is retained on the acting surfaces better, and the drop, or distance travelled by the wheel between leaving one pallet and reaching the other, can be reduced indefinitely.

The club-tooth has been generally adopted in factories for ordinary watches, and it is unquestionably less liable to damage by rough usage, but its adjustment is said to be more difficult, and for equal accuracy in timekeeping at moderate cost, it seems doubtful whether the ratchet-tooth is not to be preferred; it will certainly be less influenced by variations in the thickness of oil. But both forms possess special advantages, and the selection must be left to experience. Just as there are varieties in the wheel and pallet action, there are varieties in that of the fork and roller; but, having described that most commonly met with, I must not spend more time in their consideration, as they possess no special features of interest.

It remains for us to briefly consider the chronometer or detent escapement, as it is occasionally employed in pocket watches. Although it is without question by far the best for the marine chronometer, many competent horologists maintain that a mistake is made when this escapement is used for watches, as its action is liable to be disturbed by shocks; so that, while more expensive than the lever, it is, for a watch, not superior to it as a timekeeper. The detent escapement was devised by P. Le Roy, and applied by him to a marine chronometer in 1786. Its form was, however, modified by Barthoud, Arnold, Earnshaw, and Breguet, so that its present form cannot be claimed by any single inventor. The design usually met with is shown in the diagram. At *F* is the axis of the balance, which is, as in the previous cases, omitted in order to avoid confusion. On this are carried two steel discs, *F* and *E*, in which ruby pallets are fixed. *A* is the escape-wheel, one tooth of which is represented locked against a ruby, *b*, carried on a spring arm, *B* *b*, to which a very light gold spring, *D* *D*, is fixed. Consider the balance to rotate in the direction of the arrow, the pallet in *F* will merely raise the spring, *D* *D*, out of contact with the extremity of *B* *b*, and the balance will continue its movement until arrested by the action of the balance-spring. In the return vibration, the pallet, instead of merely raising *D* *D*, will force the entire piece, *B* *b* *D*, towards the right, releasing a tooth of the escape-wheel. A tooth will immediately fall against *c*, and communicate the impulse to the balance, and the spring will fall back into its place by its own elasticity, arresting the movement of *A*. The balance, then, receives one impulse for each double vibration, and in this respect the escapement resembles the duplex.\*

\* Having now briefly described the more important

escapements met with in portable timepieces will be well to say a few words in regard to relative merits. The first three described, verge, cylinder, and duplex, are always under the influence of the motive force, whereas, in

FIG. 16.

and detent escapements, the balance is only during brief intervals to unlock the escapement and receive the impulse.

Now, in every well made balance-spring, providing it be of sufficient length, there is that possesses the property of isochronism, virtue of which all the vibrations of an balance, of whatever extent, within limits, are performed in equal intervals and an isochronal vibration is characterized by the fact that the force exerted by it is always proportional to the angle through which the balance is turned from its position of rest. In every form of escapement there is during which the balance receives its impulse, when the character of the movement is such as to be destructive of theoretical isochronism; however, this is a regular influence on each vibration, it is quite possible to take account, so long as it does not vary beyond rate limits, and thus to secure practical isochronism. But if the impulse varies beyond these limits, vibrations are no longer performed in equal intervals, and hence we see why it is that in the detent escapements a very near approach to uniformity in the motive force is essential. Variations in this force gradually increase the difficulty in adjusting the isochronism, and proportionately increase until a point is reached beyond which it becomes impossible. The elasticity in the restraint put upon the balance by the cylinder escapement renders an isochronous

\* The mode of action of the detent escapement was further illustrated by means of a beautifully-executed working model, for which the lecturer was indebted to Mr. S. Jackson; and that of the lever escapement by a similar model, kindly lent by Mr. Tiplin.

ense, and the same may be said in a of the duplex.

considerations lead me to refer more to that much vexed question as to is advisable to retain the fusee in the ch, seeing that it has been abandoned ther watch-producing country. I hink that, in writing on this subject, makers have missed the real point at at the advocates of both views have air side. In the first place, it is not of high-class timekeeping to observe nly at intervals of say, 24 hours, ial period elapses between successive p. Absolute coincidence with the der such conditions only shows that uring the first 12 hours, when the of the mainspring were in action, was y a loss during the last 12 hours. Let , consider a going barrel and fusee while being wound up every 24 hours, ually good rate when examined at 12 hours, all question of compensa- ture being of course eliminated by them at the same degree of heat, the o being the same. The motive force g barrel is certainly less constant than usee [a fact which was practically d by means of a lever, with a sliding

weight, fixed to the winding square of a fusee watch and of a going barrel watch successively, the escapement being in each case removed. It was shown that each turn of the fusee was able to lift the lever without altering the position of the weight; but, with the going barrel, this weight had to be gradually moved towards the centre, to correspond with the decreasing motive force]. As we have seen that the adjustment of the isochronism becomes more difficult as the variations in the impulse become greater, the conclusion to which we are forced is that more skill has been required to adjust the going barrel watch. It is obvious that the amount of variation in the arc of vibration depends on several conditions that may be more or less favourable. M. Philippe found,\* as the result of a great number of experiments on going barrel watches, that this variation varied from  $112^{\circ}$  to  $65^{\circ}$  in 24 hours according to the form of spring and the mode in which it was fixed in the barrel, but he does not state the extent of the initial arc. The curve in Fig. 17 exhibits the results of experiments made by M. H. Robert† on the same subject. He found that, by increasing the motive force in one of his going barrel chronometers from 300 grammes to 2,500 grammes, the arc of vibration increased gradually but not uniformly from  $135^{\circ}$  to  $490^{\circ}$ . Mousquet,‡ in discussing these results, directs attention to the remarkable fact that, if we take

FIG. 17.

of the efficacy of the impelling force f the arc of vibration divided by the we shall find a maximum at the point g to  $370^{\circ}$  arc of vibration, and a of 1,300 grammes. Of course, this num- ced by a great variety of circumstances ith the construction and design of the , so that it cannot hold good in all he subject is well worth investigating a number of chronometers of different here seems good reason to suppose l afford a datum for determining by the most advantageous motive power case.

de with this curve of M. Robert's, I two curves, Fig. 18, representing the nge in the strength of mainsprings on all-known principle of the indicator hey are selected from a number given ier,\* and the upper curve, B B, refers for a watch going 15 days, while the A A, belongs to that of an ordinary of the same general dimensions, and, with a going barrel. A few words o explain the mode in which they are

drawn. Heights measured on the equi-distant vertical lines represent the force of the spring, and each of the equal horizontal spaces corresponds to one complete turn of the barrel. Thus, the diagram

FIG. 18.

shows that spring, B B, makes about 7 turns, and A A makes only  $5\frac{1}{2}$ . Assuming 5 turns of B B to be used in the course of the 15 days, we see that the impelling force will vary from about 2.6 lbs. to 1.3 lbs., so that if its initial arc of vibration was  $370^{\circ}$ , its final arc, judging from Robert's curve,

\* "Journal Suisse d'Horlogerie," II. (1878), p. 201.

† "Revue Chronométrique," I. (1886), p. 102.

‡ "Revue Chronométrique," II. (1886), p. 216.

will only be about  $275^\circ$ . The one-day spring is characterised by the same degree of variation. Assuming four turns to be brought into action, the initial impelling force is  $0.7\text{ lb.}$ , and that at the end  $0.35\text{ lb.}$ , so that, with the same arc when fully wound up, it will fall to about  $275^\circ$ . This spring, A. A. is evidently a good specimen for a going barrel watch, as may be judged from the flatness of its curve, and yet its isochronal adjustment will require to be correct, through a range of at least  $100^\circ$ .

I have taken the maximum arc of  $370^\circ$  as being that to which the investigations of M. Mousquet point as the best. It is, however, important to remember that they can only be regarded as applying to the particular watch or chronometer of M. Robert's that he is discussing, and in any other watch a different angle would probably be found to correspond to this maximum effect, dependent on various conditions as to the escapement, &c.

I must not omit to mention a further important advantage, secured by rendering the motive force uniform by the aid of a fusee. Probably the most neglected adjustment in a watch is that which is necessary in order to ensure an equal rate in varying positions. When lying flat the friction is, as a rule, less than in a vertical position. The rate is therefore seriously modified by the change, and, on altering the position of the watch in a vertical plane, the rate is subject to still further modification, mainly owing to the influence of gravity. It would be of no general interest to attempt a discussion of this question, but I will only add, that, if the motive force is not approximately uniform, the requisite adjustment becomes almost impossible.

The additional cost of a fusee is so slight as not to be worth considering, and it seems fair to conclude that, if in such high-class watches the fusee and chain are abandoned, additional care and skill must be devoted to the isochronal and other adjustments, and there will be an increased risk of derangement in the cleaning, &c., by any but the most skilled hands. The number of springers competent to undertake the best work is already so limited, that it seems most unwise to risk further reducing their number by increasing its difficulty.

It will be understood that I have hitherto spoken only of the very highest branch of the watchmaker's art. Whether the fusee should be retained in ordinary watches—watches, that is, which have to compete with foreign produce—involves other considerations, which I hope subsequently to refer to. But it will be a matter of regret if, in the highest branches of the watch trade, the fusee is abandoned in favour of the going barrel, as we have it in the present day. I have not seen that any advocates of the fusee in the recent discussions have drawn attention to the fact that Henri Robert, a strong advocate of the going barrel even for chronometers, urged that the fusee should be retained in high-class watches,\* because the space available for the barrel is limited, and it is therefore impossible to employ a mainspring with 10 or 12 turns, as in his marine chronometers. There have been few such earnest advocates

of the going barrel as M. Robert, and his testimony in favour of the English practice is therefore of special value. And he is far from being alone in this matter. It has become the fashion at the present day to upbraid English makers for retaining the fusee; but if anyone will study the horological literature of the Continent, he will be surprised to find how many of the best known authorities are favourable to its retention in the case of high-class watches. Besides affording a ready means of equalising the motive force, the fusee possesses yet another very important recommendation. If an ordinary mainspring be fully coiled up in a barrel so as to "choke" the arbor, forming, as it were, a solid block, and then allowed gradually to uncoil, the inner coil will remain in close contact, and the outer coil will be the first to release themselves. Thus the motive force due to such a spring will, through the greater part of its uncoiling, be modified by the adhesion between these coils, diminishing as the oil becomes thicker. The variability in the motive force is, then, itself a variable quantity. Now, if instead of being of uniform thickness throughout, the spring be suitably tapered so that the thickness increases gradually by within outwards, it is evident that the adhesion may all be caused to separate from the arbor for the tendency of the outer coil to expand is greater relatively to the mean strength of the spring, than it is in the case of uniform thickness. As all the coils are, therefore, apart through the period of winding, the irregularity due to variable friction, &c., is, in great part, avoided. But such a spring could not be used in the going barrel, since there is even greater variation in the force exerted as it runs down than in the ordinary—a fact which was prominently brought out in the experiments of M. Philippe, above referred to. The correcting action of the fusee is, therefore, the more requisite.

The difference in the mode of unwinding of the two forms of spring, is exemplified by the three Figs. 19, 20, and 21 (p. 681). The first of these shows a mainspring fully wound up, so that all the coils are in close contact. A spring of uniform thickness begins to open out in the manner indicated in Fig. 20, and must evidently occasion a considerable variability in the motive force owing to adhesion. The tapered mainspring, as used in the best English watches, will open out somewhat in the manner indicated in Fig. 21, so that the influence of adhesion is in great part avoided.

The fact that the fusee is of such value should serve as a stimulus to the invention of improvements in the going barrel, for there certainly are real objections to the ordinary form of the English watch, and a reliable going barrel, which secures an equally uniform transmission of force, is much to be desired, as it would form a starting point for the designing of a new caliper. Many changes have been suggested with which, however, I will not now detain you, and more modifications have been proposed in the escapement on account of the variability in the motive force due from any other cause; but none of these have been permanently and completely successful, compared with a well-constructed fusee and chain. Many of the objections so persistently urged against this construction, though well deserved,

FIG. 19.

FIG. 21.

FIG. 20.

as of cheap watches, are utterly unreal as is the well made and highly adjusted English. Thus, it is frequently asserted, that they *don't*, if not impossible of repair by country makers; but, I would ask, is a workman cannot repair a fusee the proper person to rusted with a highly adjusted watch at all? I am now considering the precautions that are with a view to avoid or neutralise variations motive force in a watch, it remains for me a few words in regard to the other principal of irregularity—variations of temperature. who desire a fuller discussion of the question refer to a paper which I read before the Society in March, 1879, on "Compensation." In the temperature of a balance-spring is *directly*, its elastic force becomes greater, the *oscillations* are therefore performed quicker and the *gains*; the converse is the case when heat *is* applied. Now the period of vibration of a *balance* depends on the distance between the axis of *oscillation* and the rim, varying directly with this *distance*, so that if the radius can be reduced in a *proportion* exactly corresponding with the reduction *of* elastic force, the rate will, theoretically, *be* the same at all temperatures. Such an *adjustment* has not yet been secured, but *close* approximation has been reached, and *hence* shown in Fig. 9, p. 671, is sufficient for *sketch* watches and is universally used. It will *be* that the rim, instead of being a continuous *of* brass, steel, or gold, is formed of two *parts*, brass and steel, with the former on the *outside*, and it is cut through in two places. *Gold* screws are inserted at intervals round *the* rim, and the principle of its action is as *follows*:—The expansion of brass for a given *of* temperature is greater than that of steel; *the* opposite arm, then, will become more curved *when* heat is applied, and the free extremity will *move* inwards towards the axis of the balance, *bringing* with it of course the gold screws. Thus *the* action is equivalent to a reduction in the *weight* of the balance since the greater portion *of* weight is brought in towards the centre, *the* adjustment of the compensation consists *in* so placing the screws that this effect *is* proportional to the change in the elastic *force* of the spring. Many other forms of balance *have* been suggested for use in chronometers, but *the* one described is almost exclusively used in *the* best, and secures a very high degree of regu-  
lation, if properly adjusted. But by no means all *of* watches provided with these balances are so *well* adjusted, and in very many cases a good plain

balance is to be preferred, especially in a moderate priced watch. At the same time it is probable that a well-proportioned compensation balance with cut rim, that is unadjusted, will do something in the direction of counteracting the effect of variation of temperature, an effect that, according to Delamarche and Ploix,\* amounts to about 11 seconds per 24 hours per 1° C.

The compensation balance, like the isochronal spring, is not equally applicable to all forms of escapement. Thus the verge is subject to such variable influences that the irregularities due to temperature are only a few of those to which it is liable; the cylinder and, to a less extent, the duplex, have a natural power of compensation, as already explained, just as they have a natural isochronism. But, for reasons similar to those already given when speaking of isochronism, the lever and chronometer escapements in their highest perfection require it.

Hasty though this account has been, I trust I have said enough to indicate what intelligent and skilled work is required for the adjustment of a watch, even after all its parts have been properly constructed. The degree of perfection now attained to is, in a sense, more remarkable than that of the marine chronometer, for, besides being of smaller dimensions, it involves an additional and troublesome adjustment, that for position. The productions of some of our best makers are really remarkable for their accuracy, a watch that does not vary more than half a second in 24 hours, in different positions, being frequently met with. Now, as it is physically impossible to secure absolute perfection, I am disposed to think that this must be regarded as a near approach to the limit to be attained with certainty. In what direction then must future advance be looked for? There seem to be only two possible avenues. A more general distribution of high-class time-keepers and, as tending in that direction, a simplifying of their construction, and therefore a lowering of their cost of manufacture.

Watchmakers may be disposed to doubt the possibility of simplifying the English watch, but they should remember that the history of all radical improvements in machinery exhibits a tendency towards simplicity; where the converse appears to be the case, it will generally be found that a tool or instrument has been made more automatic.

With regard to the more extended use of high-class watches, I would refer to a practice much in vogue in Switzerland, which it is stated has greatly helped to extend the trade. I mean the testing of watches at an observatory, as marine chrono-

meters are tried at Greenwich, or thermometers at Kew. The rate-papers thus obtained have doubtless been in many cases utterly valueless and misleading, owing to the fact that the commonest watch may often be found to go with remarkable regularity for a limited period, but if the trials were continued for a sufficient length of time, under varying conditions, by a properly-constituted authority, they could not fail to be of great service, as affording reliable evidence of the degree of accuracy to which our best makers have now attained. Foreign competitors have found the advantage of such guarantees, and it is impossible but that they should be of use here. They might almost be compared to the hall-mark on a piece of plate, which affords a security that cannot be gainsaid, and is independent of the faith that the buyer may or may not have in the seller.

One other point, in regard to these rate-papers, which affords food for thought to English makers, and should, I venture to think, stimulate them to renewed efforts. Dr. Hirsch, the director of the Observatory at Neuchâtel, publishes, in his annual report, a statement, showing the mean of the results obtained on watches submitted for trial. These results, for the last 15 years are as follows:—

VARIATION (IN SECONDS).

Year.	Daily.	Lying and Hanging.	Per 1° C.
1864	1.27	3.21	0.48
1865	0.88	6.18	0.36
1866	0.74	3.66	0.16
1867	0.86	3.57	0.16
1868	0.57	2.44	0.15
1869	0.60	2.43	0.14
1870	0.54	2.37	0.14
1871	0.55	1.90	0.13
1872	0.52	1.99	0.15
1873	0.62	2.59	0.16
1874	0.53	2.27	0.15
1875	0.46	1.97	0.13
1876	0.53	2.16	0.12
1877	0.51	1.98	0.11
1878	0.60	2.10	0.10

The general conclusion to which these figures point cannot be mistaken, and English makers may well envy their Swiss brethren the possession of so satisfactory a record of progress.

In concluding, I would refer to one other means by which the demand for high-class watches might perhaps be increased. As Mr. Ellis\* has pointed out, the establishment of public clocks indicating seconds, besides being of very great convenience to chronometer-makers for testing their regulator clocks, may induce purchasers to become possessed of timekeepers of high quality, as they will have the means at their disposal of verifying their accuracy. The distribution of true time is becoming every day more general, so that we may hope this influence will be felt by the trade.

[The following blocks have been kindly lent to illustrate this lecture:—Fig. 1 (on p. 666) taken from Saunier's "Treatise on Modern Horology," by Mr. Trippin; Figs. 10 and 11 are from Sir E. Beckett's "Clocks, Watches, and Bells" (Crosby Lockwood & Co.), 1874; Figs. 9 (p. 671) and 16 by the editor of the *Horological Journal*; and Figs. 12, 13, 14 by Messrs. Spon.]

## DOMESTIC ECONOMY CONGRESS.

(Report continued from p. 672.)

The meeting of Friday, 24th June, was the Society of Arts, the Viscountess STEIN in the chair, and Lord ALFRED S. CAMERON.

## SECTION D 1.—RULES FOR HEALTH AND MANAGEMENT OF THE SICK ROOM.

Lady Strangford read a paper on "Teach of Health in Elementary Schools."

Sir Henry Cole said that nothing more simple, or convincing, even to Whitehall, had been read in the Congress. Lady Strangford entirely proved her case, that a knowledge of hygiene would lead most effectually to the acquisition of other education in the shape of reading, writing, arithmetic. The ladies of the Congress, and the Lords of the Council, no peace until they learn by heart Lady Strangford's paper.

Mr. Chadwick recommended the formation for practical teaching in this direction, an account should be given of the working of it. Forth mere generalities was not sufficient, and to be of any value should be proved and tried. acquainted with a lady who had laid down allow no colds in her house, and her recollection, entailed care on her part that the members of her household should not remain in damp clothes, and that all other indiscretions should be prevented.

Sir Henry Cole thought if women would run households by laying down such rules as should be banished, and could carry them out, we should have gone very far in the direction.

Paper read by Miss Mary Martineau on "the Laws of Health in Schools."

Mr. Chadwick said knowledge so exceedingly should be particularly addressed to the superintendents, because even in the construction of schools, a great deal of information was wanted. The very structure in which conducted their deliberations, and which he large sum of money, had proved to have been in violation of sanitary laws, and a lady recently made very ill from sitting over a grate in communication with an old sewer had been allowed to remain there. Needless the defect was soon remedied, and the sewer up. Evidently, a body so unacquainted with health, required considerable instruction. schools connected with that body, where he filthy children massed together, in defiance of rules, the cases of sickness reached 30 per cent in another, conducted in accordance with the health, the per-centage of illness was only 10 per cent.

Paper read by Miss Freakey, M.D., on "Rules of Health in Elementary Schools."

Mrs. Sutherland Orr's paper, on the "Duty of Introducing a Practical Knowledge of the Health in the Lower Standard of School Education," was read by Lady Strangford.

Mrs. Priestley entirely concurred in the paper really embraced her own idea, that the subject much elaborated with science to be of any real use. If we could direct our views and our teaching of a good deal of science with which were mingled, more practical results would be obtained. It was, after all, a very simple matter, and should be taught in the simplest manner, especially to children.

Cole quite agreed that too much science d in teaching children from seven to ten

t thought a recommendation should be Education Department to put forward a first extra subject in boys' schools should, just as the first extra subject in girls' be domestic economy. Two extra sub-taken in all schools under the Depart- never heard of French and Latin been been suggested.

ole said that they were so taken.

t thought possibly a particular reason r that in London just as in Kidderminster, ght drawing, because it would afford them gaining a good and respectable livelihood, being much in request by the manufac- own. Certainly no subject could be taken estic economy. One necessity for teach- y was the great expense of diagrams, for ext-books, though they enable teachers to pectors, could not bring the matter home 1. Prizes and certificates might be given rashing, and other branches of domestic men would soon learn to look out for the wives among the young women who held s.

y of Alderley had had a long experience of aching, and had as far back as 18 years ago of girls in the country on physiology, and ed the interest they took in the dissection the village butcher, at her instance. She ight in St. Luke's parish, London, and to obtain animal specimens, she recom- upils to notice ligaments and tissues of xposed in the butchers' shops. She had r children at home, and had in all cases hildren take a great interest in these asily understand them. It was often said dren were inferior to those of richer people ), but it should not be forgotten that they teaching by seeing their mothers handling od, which children in the higher classes i, and she had found children of the lower ute.

ay knew something of the alums of burgh, and Leeds, and could speak to the f the working class of children. After r intelligence toned down by their being ). A rational basis should be given to he acts they were to perform, and when ation was given them, they were taught pidly.

ole considered these subjects should not s extras, but as primary subjects. The unchangeable like the laws of the Medes and domestic economy might yet find before reading, writing, and ciphering. th Miss Peechey that the brightness and f women of the working classes were rriage, and the tyrant, man, was no doubt r it; but if boys were taught something of they might do more when men to alleviate of their wives.

r had seen in some of the towns of the s, classes taught by means of models, some ing given out for the children to say during i they were performing, such as making ing open windows with the object of im- eaching on their memories. Little things t way in youth were remembered in after a good might be done by the publication sses of that character compiled for the use

Mr. Pope said certificates were given by the Society of Arts, and he knew, as a lecturer, how they were striven for in classes. Every one of his ladies in an ambulance class had taken first-class certificates, but he was sorry to say the men had failed disgracefully. In these matters young ladies easily took the first place.

Mr. Edwin Chadwick maintained, as a fundamental axiom, that the home and the child were the chief domain of woman. If the tenour of the papers read by ladies at this Congress of Domestic Economy were fairly considered, it must be admitted that, on the whole, those papers were calculated to extend and vindicate that domain by their advocacy and demonstrations of the useful and the practical, as by living and applied science against the dead languages, and the theoretical and useless too long intruded by scholiasts.

Paper by Miss Louisa Twining, on "The Prevention of Disease," read by Lord Alfred Churchill.

Paper read by Mr. Pope, "Health in the School-room."

Madame Lofving said it was not sufficient to teach people the principles of domestic economy; they should be taught that they had within their own bodies organs for the performance of physical functions which were in themselves sufficient for the preservation of their health. As far back as 1830 that had been done in Sweden by Dr. Ling, and the State there soon took up the matter as one vital to the common weal. The Swedish military system was based on that gymnastic training, and another branch was medical gymnastics, for the cure and alleviation of injury and disease.

Mr. Chadwick had received testimony from officers in the Swedish Army that, by teaching the boys on Ling's system, it had been found that the period of service could be shortened, and that the actual force of the army had been largely increased. Even the Russians had adopted Ling's system.

Paper by Mrs. Johnstone (of Hastings), on "Prevention of Epidemic Disease," was read.

Mr. Chadwick pointed out that the essence of the paper was home treatment of disease where isolation was possible, as in the upper rooms of a house; and the possibility of avoiding contagion was shown by the fact that nurses often succeeded in protecting themselves for 20 years.

Sir Henry Cole said school-rooms ought not to be in so bad a condition as had been described by Mr. Pope, as the inspectors had power to report upon them when not up to standard; but the fault lay in the absence of a system on which to proceed. How imperfectly the inspectors' work was done was shown by the fact that in 1879 they had reported only four schools as teaching cookery, but this Congress had ascertained that there were no less than 300 in which that was done throughout the country. That kind of inspection was a work to which women alone could pay sufficient attention; and the members of the Congress should never rest until the education for home-life, which was the province of women, was provided for before the ologies were taught.

Lady Strangford made a few concluding remarks, and the meeting separated.

At the afternoon meeting, Lady STANLEY OF ALDERLEY occupied the chair, and the Rev. J. P. FAUNTHORPE officiated as assessor.

#### SECTION D 2.—THRIFT.

Paper read by Lady Stanley of Alderley, on "The Girls' Home Certified Industrial School."

Paper by Mrs. Townsend, "The Girls' Friendly Society," was read by the Rev. J. P. Faunthorpe, M.A.

Paper by Lady Stuart Hogg, on "The Metropolitan Association for Redeeming Young Servants," was read.

The Rev. J. P. Fauntleroy, in inviting those present to join the Servants' Friendly Society, urged that servants should be encouraged to open accounts in the savings' bank as an important means of bringing about the reforms advocated. One way of inducing children—and possibly through them their parents—to begin to save was the distribution among them of post-office stamp slips.

The Rev. Mr. Lang had spent a long time in India, and had had considerable experience in teaching and training women in the East. He had found that the great difficulty was always that insufficient attention was paid to the teaching of domestic subjects. The example of this Congress would not be confined to England, but would extend to the East; and no country more required to have inculcated among the people the principles here put forward than India.

Dr. Mann said that nothing too strong could be said in favour of the Girls' Friendly Society, and assured the members that they would be doing a good work by inducing as many as possible to join it.

Paper read by Rev. W. L. Blackley, on "National Teaching of Thrift and Providence."

Mr. G. C. T. Bartley, manager of the National Penny Bank, reminded the Congress that their object was not so much the laying down of principles on which the world was to be reformed, but to show, in a practical way, how children in schools could be taught to be thrifty. One of the best means of doing that was by giving a simple lesson in every school on the Penny Savings Bank, and on the Post-office Stamp Savings Bank. Post-office forms might be kept in schools, and stamps also, on which the children might be induced to expend their half-pence. Thousands would in that way be made thrifty. Children could easily be made to understand the principle of the savings bank, and they would soon begin to feel it a point of honour to have a little account there. That kind of work might be done with great advantage while waiting the arrival of the compulsory system shadowed forth by Mr. Blackley. Waste was a subject which was seldom looked after in schools, and very few teachers or children really understood its effects. Thrift was not necessary for the working classes alone, but for all. Children could easily be shown that waste damaged the person guilty of it and the community alike. Life assurance should also be explained, and could very easily be made intelligible by the teachers. This Congress should not make the mistake of carrying out anybody's special scheme of thrift, but should take care that simple practical instruction upon it was given to children in the schools.

Dr. Mann read a paper on "The Formation of Habits of Temperance among Girls."

Sir Henry Cole, without saying anything about temperance or intemperance, would revert to what was best to be done for teaching thrift in schools. Since 1847, the Education Department had made grants for the purchase of lesson and text-books; but they had in fact lost their soul, had no belief, and, as Sir J. Kay-Shuttleworth had said, "had become a mere red-tape administration of Parliamentary grants, by rigid rules, with the intention, above all things, of preventing the growth of the charge."

Lady Stanley of Alderley could not remain quietly by and hear the department disparaged, knowing how much had been done by it during the last fifty years.

Sir Henry Cole insisted that we had gone back within the last thirty years in our notions of how to teach children to be thrifty, and that result had arisen from our having got rid of all responsibility of advice.

Sir Walter Stirling was glad to see ladies in this work, and that they had so efficient a leader as the Lady President. It was hard to expect without money to exercise the virtues of thrift, should have chiefly at heart to teach young girls to do their duty, and to follow, even in household the golden rule of doing to others as they were by.

Mrs. Ross, in reference to the necessity of temperance in schools, gave an instance of an who, on asking the use of water, failed in a while to obtain an answer that it was used to drink, from a medical point of view they should be made aware with the fact that the drinking of small quantities of water was beneficial in cases of exhaustion.

Mrs. Charles read a paper on "Food-wash houses and District Schools."

Dr. Frances Heggar read a paper on "The Effect of Effective Diet in Workhouses and Prisons."

Mr. Mann read a few statistics from a recent committee appointed to inquire into dietaries of sons of England and Wales as to the cost of the quantities consumed.

Paper by Miss Prouser, on "Boarding of Children," was read by Mr. Tennant.

Rev. J. P. Fauntleroy (as Assessor) on the members on having had the opportunity so many valuable papers as had been read, this would be a good omen that the Congress as far as the Section "Thrift" was concerned be wholly fruitless. He referred in compliance to Mr. Blackley's paper, and the practical made by Mr. Bartley, adding, that the latter was in error in supposing that this subject already taught in schools. Lady Stanley's recommendation that post-office stamp forms be distributed among the children would be particularly valuable, and Dr. Mann's paper on the subject of temperance, bore closely and habits of the people. Too much importance not be attached to the desirability of our Girls' Friendly Society, whose praiseworthy that young maid-servants coming from out to London might find that they were not entirely alone in the wide waste of the metropolis.

Lady Stanley of Alderley, in addressing to a few concluding remarks, specially mentioned of the late Mr. William Ellis, who had been the subject prominently before young people by his efficient style of teaching, much in he taught.

The Rev. Newton Price proposed a vote of Lady Stanley for her services in presiding Section.

Dr. Mann, in seconding the proposition, mentioned a small work published on the subject by the late Mr. Ellis, for use in schools.

The vote of thanks was passed unanimously, and the meeting terminated.

Friday evening, 24th June, 1881.

#### TEACHERS' MEETING.

The Rev. Newton Price, M.A. (presiding) managers of the Congress had felt the important the sentiments might be of ladies more or less connected with the new schools, and in some cases with the former opinion, it was desirable to ascertain the of teachers, and to secure their hearty co-operation, more especially as there was a feeling that were not altogether so favourable to the

a economy as might be expected. He shared the feeling to be much exaggerated, & here and there teachers looked upon the making domestic economy as derogatory to it. The committee, however, were anxious to elicit the opinions of the teachers. They desired not to be held responsible for a system which had been said by speakers, and have been a little painful to teachers. If our country depended to an enormous extent on the way in which teachers did their work, and the influence they exercised over the growing up under their care. They were increasingly the most influential body in the privileged classes, as they were called, but a mere handful, and having the education of the people in their hands, they did really an enormous influence. They were quite sure, therefore, that in pressing upon their attention they would recognise the value of the work in a work which they felt sympathy.

Mr. Pries, one of her Majesty's Inspectors of a short paper on his "Experiences in the of Needlework."

Mr. Cole said the ladies of the committee had adopted the very plan mentioned by Mr. Pries, but though their suggestion had been received by the educational authorities with interest, they were not daunted, and needed to secure a still more representative needlework next year. Possibly the committee of the attendance at this teachers' meeting attributable to the fact that domestic and no part of the subjects taught by male teachers, therefore, were not perhaps much interested.

It had been hoped that a representative of the Education Department would have been present, but he was not particularly favourable to the scheme.

Mr. Pries begged leave to state that, although not in his private capacity as an individual, he had been invited by the Department to give the Committee in his power. Most of the teachers were far away engaged in their duties throughout the country, and those who were in London, were extremely hard work at the present time, so that their absence must be attributed.

Mr. Cole had been at considerable pains to secure a special benefit of the teachers invited to the meeting. Two specimens of certificates formerly given to teachers, and endorsed annually by the Education Department, were shown to the teachers with their opinions on the conduct by the schools in their charge. Upon those certificates were made. At present it seemed to the inspectors that the condition of the school was good, or had improved, and so on, but saying nothing whether the buildings were in proper condition, or as to the teaching of the subjects. He would like to know whether the teachers did really make a return upon all the money governed the payment of public money for the Code. When the education scheme was started in 1840 by Dr. Kay-Shuttleworth, it was granted in the most thorough and simple manner, and signed as was the one he had before him in 1848, by the superior authority over all the schools, the President himself. Of that thorough and simple document should be which affected a teacher and prospects, and, further, it enabled the teachers in educational matters to know more than did the modern certificate. It certified the knowledge possessed in each of the subjects in it in the most exhaustive manner.

A Lady inquired to what kind of school the certificate referred to?

Mr. Henry Cole said it had reference to a national school in the neighbourhood of London. At present the certificates were issued in the most general form, simply of three grades. For the fact that whereas, 40 years ago, teachers had real, genuine certificates given them, by some process altogether unknown those certificates had been turned into the present windy, useless documents, he was puzzled to account, but it was a mystery which he hoped they would get at the bottom of before long. He would ask teachers themselves, in the first place, which form of certificate they preferred; and he certainly thought that if the public were not to be allowed to know what they received for the money expended in training teachers, the sooner the better the system of giving certificates was abolished altogether as a mere fiction.

The Rev. Newton Pries was of opinion that the teachers would probably prefer to have their acquirements stated; and there could be no doubt that managers of schools and the general public would also like to have the facts stated for their information.

Miss Guthrie Wright thought the form of certificate giving full particulars was based on the better principle.

Mr. Hugh Clements said that, as a rule, teachers objected to unnecessary interference with their private affairs, and considered that a too elaborate certificate would disclose more than they desired, or it was necessary should be known. Their training at the college was a sufficient guarantee that they had received a good education. On the other hand, they desired to have certificates on particular subjects, such as drawing.

Mr. Henry Cole remarked that that certificate was given, not by the Education Department, but by the Science and Art Department.

Mr. Clements continued that teachers complained very much that the grants they now earned were so cut down that it was not worth their while to teach drawing at all. £400,000 a year was paid by the public, and out of that the Science and Art Department expended in grants only some £40,000, the rest being swallowed up in the expenses of administration. Teachers often spent their whole day in making up forms, when their time and attention would be much better devoted to their scholars and assistants. Continual alteration was made in the forms sent out to the teachers, and there was really no system followed by the irresponsible members of the School Board.

Rev. Newton Pries observed that Mr. Clements was under an entirely wrong impression with regard to the immunities and privileges of the School Board. A very useful question had, however, been started by him, that of making the teachers' payment depend very largely upon results. Personally, he (Mr. Pries) had been much opposed to the system for many years, and in the schools with which he was connected it had been entirely got rid of. It had been found that the payment of a lump sum was much more satisfactory to the teacher, whose mind should be left entirely free from monetary anxieties. He certainly considered that teachers' salaries should not be left dependent on the grants.

Mr. Barber, of Cheltenham, one of H.M. Inspectors, protested, in reference to the comparisons made between inspectors, against the notion too commonly held, that when the per-centage at examinations was found to have fallen, that the inspector on that occasion was the wrongdoer. There was no reason whatever why the assumption should be made.

Mr. Stephen Mitchell recognised the difficulty they had to deal with, as to what ought to be done, and he failed to see how it ought to be done, though he had visited schools of chemistry, and examined the methods

of teaching. He thought it was especially ladies' work to suggest how the children of the operative classes could be so instructed that they might, as they grew up, be useful to their parents in home matters, and afterwards be better able to provide for husbands and children, by that means bringing up a healthier race of people. As it appeared that no definite resolution was to be passed in the matter, he was afraid that this, like all other Congresses, having led to much talk, would have no practical result whatever.

Mr. Clements thought Congresses were instrumental in changing public opinion. When the people became convinced of the utility of new methods, and desired that they should be put into practice, they soon brought the pressure to bear on the Government for the adoption of the necessary measures. On so important a subject as this they could not have too many Congresses and meetings of all kinds, affecting as it did, the food of the people.

Sir Henry Cole thought the use of Congresses had been unjustly depreciated by Mr. Mitchell, and quoted the opinion of Professor Huxley as to their value, as Government always lagged a little behind public opinion, and Congresses were a most efficient means of pressing them on. He then proceeded to read a list of the teachers who had gained prizes offered by the Society of Arts.

#### LIST OF AWARDS OF MEDALS FOR PAPERS IN THE TEACHING OF DOMESTIC ECONOMY.

1. "The Teaching of Domestic Economy," by Miss E. M. Brant, Board School, Berkhamstead, Herts.
2. "The Itinerant Method of Teaching Domestic Economy in Public Elementary Schools," by William J. Harrison.
3. "How I Teach Sewing," by Miss Jane B. Curry, Episcopal School, Dumbarton.
4. "Instruction in Needlework," by Miss Eliza Jane Allen, St. Mark's Girls' School, Belgrave-gate, Leicester.
5. "Needlework considered under Four Heads," by Miss Sarah A. Hall, National Schools, Beauchampton, Bucks.
6. "Some Points considered in Teaching the Second Branch of Domestic Economy," by Miss Harriet Martin, of Whitelands, Chelsea.
7. "How I teach Practical Cookery," by Miss Bunce, Episcopal School, Dumbarton.
8. "Practical Cookery in Elementary Schools," by Miss A. M. Griggs, School of Cookery, 6, Shandwick-place, Edinburgh.

The meeting then adjourned.

Saturday, 25th June, the Countess of DERBY in the chair.

Sir Henry Cole read the report of the Executive Committee to the Council of the Society of Arts. [Printed in Council's Report, ante p. 653.]

The adoption of the report was moved by Lady Derby, and seconded by Lady Stanley of Alderley.

Sir Henry Cole said that by agreeing to the substance of the report, the ladies present would add to its force when sent before the Council, with the weight of their *altruism*.

The resolution was carried unanimously.

Sir Henry Cole then said the only remaining work for the Congress to do, was to express their approval of the announcement that they should go to the Lords of the Council with such representations on this subject, as would be likely to influence them in making an alteration in the Code. The request, which had been already signed by the Duchess of Leeds, Lady Stanley of Alderley, and other ladies at the Needlework Conference,

was as follows:—"The Executive Com requested to make arrangements for holding exhibition of Plain Needlework, in 1882." It was to be communicated to my Lords, and they would be asked to receive a deputation who would express their views.

Mrs. Deane Craven said she had been in it was only proposed to hold the exhibition years. Exhibitions of industrial work are held only at intervals of ten years, but in that character it was necessary to exhibit and to show that the work was attended to. It had been considered, therefore, that to have exhibitions every two or three years would interest to needlework in the schools, and it pledged to five years.

Sir Henry Cole said the request had been sufficiently authentic exhibition to take place. That could only be done effectually through the whole machinery, and everything at the South Kensington Museum. There insuperable objections probably to periodic being held if they were desired.

A Lady suggested that it might be useful were asked to send up reports of what they doing.

Sir Henry Cole said that was just what had engaged to do. They proposed to extensive inquiries, and that would be the of the Executive Committee. As the last Education Department had only given schools where cookery was taught, the Commission it very imperfect, had drawn up a set of the point, which they had been permitted Education Department to send to the inspectors and the result showed that in most instances cookery was taught. A most amount of information besides, which before Parliament, would be published in the document they had prepared. He proposing a vote of thanks to Lady Derby passed unanimously, as was a similar vote for her services to the Congress.

Sir Henry Cole, before declaring the Congress at an end, was desired by the Lady say that it had not been from want of objects that she had not previously attended confirmation of that statement he would she had, in another practical way, shown assist in the carrying on of these Congresses.

The Congress was then declared at an end.

## MISCELLANEOUS.

### SECONDARY BATTERIES

The following description of the *Plante* secondary batteries is taken from the editor of which paper has kindly lent (from *La Lumière Electrique*) to illustrate it. (p. 687) represent the *Plante* cell.

The preparation is as follows:—Two sheets laid the one on the other, separated by an india-rubber, the whole being rolled up as at 1. The roll having been completed, the cylinder its formation is withdrawn, and it is covered a wrapper of gutta-percha, and inserted in a jar filled with water, and 1-16th part electric current is then made to pass the cell, oxygen is given off and produces a cushion of peroxide of lead in one sheet; 1

FIG. 1.

FIG. 3.

FIG. 2.

at the other sheet. If the current with which has been charged be cut off, and the two sheets acted, a current will be produced owing to the

FIG. 4.

of the oxygen, which leaves the sheet where it is insulated and attacks and oxidises the other sheet. This secondary current, which is very small

at first, gains strength each time the operation is repeated; in course of time the surfaces of the sheets are changed, the one being covered with a cushion of peroxide of lead, the other with lead reduced to a spongy mass. The cell is now complete, and in a state of electrical accumulation.

Subsequently, M. Planté tried the plan of separating the two sheets of lead by canvas, the cell taking the form of Fig. 2. He next found that it was necessary to leave a small space between the sheets to provide for the escape of the gases which were produced at the end of the charge; subsequently, india-rubber bands were employed in preference to canvas. M. Planté also tried carbonate of lead, minium, &c., but without improving upon the results already obtained.

The Faure battery is very similar to the above, and is constructed thus:—Two sheets of lead are taken, 0.20m. large, the one about 0.60m. long and 0.001 thick, the other 0.40m. long and 0.0005m. thick. Each of these is furnished with a strong strip of lead at one of its ends. Each sheet has a layer of red lead spread on its surface, the lead being made into a paste with water, the larger sheet having about 800 grammes on its surface, and the smaller 700 grammes. On each surface a sheet of parchment is laid, and the whole is introduced into a sheathing of thick felt. The sheets are laid one above the other; at the same time several bands of india-rubber are placed in an oblique fashion, as shown in Fig. 3. The roll is placed in a leaden jar, strengthened by copper bands, and supplied in the interior with red lead and felt. The cell then presents the appearance shown in Fig. 4. One of the pieces of lead which jut out is curved and soldered to the outer jar, acidulated water is put in, and the battery is ready for work.

Some experiments with an extemporised Faure battery have been carried out recently in the office of the *Scientific American*, which are described as follows:—"In attempting to follow M. Faure's plan of construction, some

difficulty was experienced in making the red lead remain in place during the rolling up of the two electrodes. Therefore, the battery was constructed of square plates of lead, each having an ear projecting upward from one side, for attachment to a binding post. This plan succeeded very well, the flat plates having the advantage of retaining a great quantity of red lead and of being easily formed into a compact pile. The plates employed were of pure lead foil, having the thickness of a post-card, a width of 7 inches, a height of  $7\frac{1}{2}$  inches, with an ear projecting from the top  $1\frac{1}{2}$  inch wide and 3 inches high. The total effective surface on both sides and edges of each plate was 100 square inches. Ten such plates were sufficient for a single element for ordinary uses, and such an element may be fairly charged by means of four gravity cells, but a stronger current is much quicker and more satisfactory. The method followed in building up these secondary elements was as follows:—After cutting out a sufficient number of lead plates, pieces of canton flannel, 15 inches long and  $7\frac{1}{2}$  inches wide, were cut; and, finally, as many sheets of blotting paper,  $7\frac{1}{2}$  inches square, as there were lead plates, were provided. The next step was to prepare a thick paint of red lead by mixing the dry pigment with water containing one-tenth of sulphuric acid. This paint had a consistency of paste, and was applied thickly to one side of the sheet of lead with a common flat paint brush.

The canton flannel having been painted to within one-quarter inch of all its edges on the nap side, the lead was laid, painted side down upon the painted canton flannel, when the other side of the lead was painted, and the cloth was neatly folded over the lead, completely enveloping it with the exception of the ear at the top, and projecting about one quarter inch beyond all the edges of the lead. The lead with its envelope was then laid upon a level board, and another plate was prepared in the same manner and placed over the first, with an intervening layer of blotting paper, and with the ear placed opposite the ear of the first. Other lead plates were added in the same way, with the interposed sheet of blotting paper, and with the ears alternating in position. When ten plates had been placed together in this manner they were clamped together with two or three elastic bands, and the ears were brought together and passed through a slit in the wooden cover of the containing cell and bent down upon the top of the cover. They were then pierced and traversed by the screw of a binding post which entered the wood. In this way each pole of the element was furnished with a binding post, and at the same time firmly secured to the cover. The cell was then partly or wholly filled with acidulated water—water 10 parts, sulphuric acid 1 part—and after the cloth and blotting paper had become saturated the element was connected with four gravity cells. In one hour the element had stored electricity sufficient to heat  $1\frac{1}{2}$  inch of fine platinum wire to redness, to work a magnet strongly, and to run at a high rate of speed for fifteen minutes a small electric motor that requires at least ten gravity cells to operate it. After this preliminary experiment a number of the new secondary elements were prepared in the same way and charged separately with a dynamo-electro machine. One element of ten plates, after receiving the current from the dynamo for ten minutes, operated the small motor above referred to, for something over three hours. Another ten minutes' application of the current from the dynamo charged it so that after eighteen hours of rest it yielded a current which seemed as strong as when it was first charged on the previous day; but a time test proved that it was incapable of running the motor for quite so long a time as when the current is used soon after storing.

The Faure battery was exhibited for the first time in England at the *Concessions* at King's College, on Saturday, 2nd inst., when it was used to light the Swan and Lane-Fox electric lamps.

## PLANTAIN TREE.

Mr. L. Liotard has prepared an elaborate n d m on the plantain tree (dated Calcutta, Jan 1881), of which the following is an abstract:—

Dr. Balfour, in a note dated the 15th Octob has noticed the Agricultural Department depu memorandum on fibrous materials in India sui the manufacture of paper; and he special attention to the chapter on the plantain tree species of this tree, or rather, plant, have be in India from the most remote times; but s ducer of marketable fibre, the only species w yet come to note is the *Musa textilis* of the I Islands: this yields the fibre known in com Manila hemp.

The introduction of the *Musa textilis*, in 18 from the Philippine Islands into the Madras P is described in the printed memorandum, w shown that attempts made to extract the fib country for commercial purposes proved although thousands of tons of it were being every year in the Philippines.

There is no doubt that the Manila hemp pla *textilis*) grows as well in British India as oth of the plantain genus; and Dr. Balfour j that British India could in a couple of years i London market with all that it could take hemp fibre. He therefore observes that the p benefiting British India by creating an ex from it of the extent and value above indic well incite to considerable efforts to attain su he suggests that the attention of the Board missioners of Revenue, and of the Agri-Ho Societies might be re-directed to this plant.

It is known that the *Musa textilis* was r success in Calcutta as an experiment in 1822, 1840; that fibre was extracted from the p made into a neat cord no way inferior to Eng cord; and that a project was then put forw establishment of the manufacture of paper fibre; but we do not know how or why the p not carried out. The projector, we learned, v of the British colonies in South America.

We know also that in the Madras Pres efforts to introduce the *Musa textilis* were extended nature, beginning from 1858; the planting proved very successful; that num plant were introduced and reared; that the tracted therefrom were cleaned and experime and were found to possess considerable st gloss; to be very clean, and fit for tal also that success in the rearing of the s especially attained in the Wynaad, wher remarkably well and was multiplied in larg in several of the coffee estates both easily an and that there was no doubt as to the va fibre, but that the efficient and cheap pre the fibre remained an unsurmountable difficu

In the Andaman Island also the plant w fully reared and propagated, and fibre wa but the process of extraction, which co steeping the stem until decomposition set probably a very bad one, and consequently which was reported to be creditable in othe was found harsh and wanting in strength.

The experience gathered thus seems to p discovery of some satisfactory process for the fibre cheaply and efficiently as the essenti nary to any extensive Indian trade in the pro mode of treatment followed in the Phil first be noted; the British Consul at Mani it as follows:—

"When the trees have matured, or are cutting, they are cut down about a feet ground; and the labourer then proceeds to the layers from the trunk, which are cut into

inches wide, or say, three strips to each. These strips are then each drawn through a blunt knife and a board to remove the vegetable matter from the fibre, which is then in the sun to dry. As soon as it has been fully dried, it is ready for the market. The use of the fibre depends entirely on the care in drying it, as, should it be exposed to rain, thoroughly dried, it becomes discoloured, or a brownish tinge, and loses the strength to a great extent.

Regarding machinery, several attempts have been at have proved unsuccessful, to invent a suitable machinery for cleaning, to supersede the primitive still in use, which consists of a few cross grating bars of bamboos, to which are fastened the cleaning knife, the fibre, or rather, the strips, being introduced between the board and the bars, which latter is then held down by a string to a cross bamboo, on which the foot of the operator is placed, and the strip is pulled through, removing all the vegetable matter. The usual quantity of Manila hemp which is exported by this means in the Philippines is reported to be 40,000 tons, of which the United Kingdom takes about half.

For any improved method of extracting the fibre, or being not discoverable, there does not appear to be any reason why the method of extraction followed in the Philippine Islands should not be adopted in India, with any modifications which experience might suggest.

I myself tried an experimental process, in which I was guided by the considerations below.

First of these was the structure of the plant. It consists of layers of fibre united together longwise by cellular tissues which contain a very large amount of mucilaginous and pulpy matter in which colouring matter is present. There are in the trunk three distinct qualities of fibre—it is strong in the outer layers, fine and silky in the interior, and of a middling quality in the intermediate layers, while the central foot-stalk contains no fibre. The mid-rib of the leaves also contains fibre.

Secondly, the proper time for extracting the fibre is of importance if the fibre is ultimately to be used for cordage or textile manufactures, but of less importance, perhaps, if the fibre be destined for paper-making. The proper time is when the purple colour of the leaf is about to rise, but has not quite appeared. It is then that the fibres are in their best condition, for that, the fibres will be immature, after which they will have lost their strength.

Thirdly, the appearance of the fibre. All fibre is according to the degree of its cleanness, its uniformity, and its uniform structure; and if, in addition to these qualities, the fibre is of fine texture, it commands a high price. It is thus necessary to select the fibres. The easiest way to do this is, after the plant is cut down, to strip layer after layer from the trunk, each strip being about two inches wide, and the layers according to the fibres they contain, will be found to present the features above mentioned.

The stripping is very easily effected by the use of the help of a knife, and has the advantages of securing uniformity in the fibres by classification of facilitating their extraction, as will presently be explained. The mid-rib of the leaves should be cut into four parts to facilitate the crushing, and the leaves kept apart from the produce of the trunk.

Fourthly, the time taken in the operations. The fibre should be utilized on the day on which they are cut, and they should be manipulated in the shade. Some are of the opinion that if the fibre be not forthwith ex-

tracted, the fleshy or sappy compounds, if subject to wet, will decompose; whilst if they are exposed to the action of the sun's rays, the fibre will be discoloured. Further, the immediate removal of all extraneous matter reduces the bulk of the product, and thus decreases the cost of transport to storage centres.

Looking to the benefit that will result to the country, should success be attained, and the very small expense that will in any case be required, the Government of India may perhaps be disposed to give this process some effective trial in some convenient localities. If so, it might be well to make a beginning in the Wynad, where the true *Musa textilis* has been successfully introduced and propagated, and where, I believe, large numbers of the plants exist.

A further suggestion which I would venture to make is, that experiments should be made with some of the native varieties of the plantain tree, those varieties being preferred which grow on hilly land, as these contain more fibre than the varieties on low-lying flat ground which are valuable in other respects. Thus, in the Governments of the North-Western Provinces and the Punjab, trial might be made with the species of the plantain trees that grow on the lower ranges of the Himalayas, that is, below Mussoorie, in the lower tracts of the Nahan State, in the Umballa district, and in Kangra. It is just the species that produces insipid fruit, sometimes with seed inside, that will be found to yield a larger per-centage of fibre.

In Bengal, Bombay, British Burma, and the Central Provinces the indigenous species growing on the high lands might usefully be experimented with, the above remarks giving an idea of the kind of plants to be selected.

The real obstacle, however, to the successful introduction of new fibre materials into our export trade is the cost of railway fare. On this point I will reproduce here the remarks which I made in the memorandum I referred to at the beginning of this note:—

"The cost of the carriage, not only of fibres, but of all raw and natural products of India, from the internal districts to large centres of population and to export marts, prevents such products from being utilised, and a large source of income to the country is thus neglected. We find that Mr. Rendell, in his evidence before a Parliamentary Committee, stated that the cost of carrying a ton of goods for a mile is, on the East Indian Railway line, '28d., and the average cost on nine lines '376d., or  $\frac{1}{4}$ th of a penny. Before long, he says, the cost on the East Indian Railway of carrying a passenger, or a ton of goods, for a mile will not exceed  $\frac{1}{4}$ th of a penny or  $\frac{1}{4}$ th of a penny respectively; and though that rate may not be attainable on lines less favourably situated as to fuel, gradients, and quantity of traffic, the cost of transport ought not in any case to exceed  $\frac{1}{4}$ d. per ton per mile, and  $\frac{1}{4}$ d. per passenger per mile. 'Experience,' Mr. Rendell said, 'shows that a reduction of rates, especially for passengers and cereals, is always accompanied by a large increase of traffic.' He added that, as consulting engineer of the East Indian Railway and States Railways, he would strongly advocate a reduction of rates, and he was certain that such a policy would ultimately prove remunerative. There can be little doubt that, as regards fibres also, the same beneficial results will be produced by a reduction in the rates."

The Bombay Chamber of Commerce, in a letter addressed on the 9th May, 1879, to the Famine Commission, said:—

"The high rates charged for the conveyance of goods have prevented Western India from reaping all the benefits which were reasonably expected to flow from the introduction of the Great Indian Peninsula system into this Presidency. This statement is borne out by the fact, that on a recent occasion, when a reduction of their grain rates was made, a very large development of traffic immediately occurred and has steadily progressed. In September, 1875, the Great Indian Peninsula Rail-

way reduced their grain rates from the producing districts in the Central Provinces of 6½ pias per ton per mile, being a reduction of 30 per cent. on their previous rates. This reduction left the rates still considerably higher than the East Indian Railway Company's rates, but it led at once to a very great increase in the traffic."

The Bombay Chamber of Commerce then went on to quote figures of exports in illustration of the rapid increase in the traffic, and added:—

"But these illustrations of the effect of reduced rates prove that even railways in India may be of little avail in fully developing the resources of the country if the rates for the carriage of produce are not reduced to the low scale necessary to attract the produce of the districts through which they pass."

There can, therefore, be no doubt that a reduction in the rates of railway carriage for the fibrous, as well as other, products of India would have a beneficial result.

I venture now to suggest that the question be referred to the Public Works Department for early consideration. If a reduction of rates for all fibrous materials is not feasible at present, I would earnestly suggest that such materials, when destined for paper manufacture at least, be allowed to be carried over the railways at rates lower than those now imposed. A gentleman who is engaged in the business in Lower Bengal writes to me on this subject as follows:—

"A great deal of raw material, which could be utilised for paper-making, cannot be brought down by rail on account of the high freight payable according to the present goods tariff of all railways in India.

"Amongst the well-known materials used for paper-making, take, for example, aloë-fibre, jute, hemp, flax, rag, and waste papers; all these, when loosely packed, are at present put in Class 2, the rate of which is 50 pias per 100 maunds per mile. Mounj or any other grass or plaintain leaves, when loosely packed, belong to class 3, and are charged 6½ pias per 100 maunds per mile. Plaintain leaves and grass have an additional obstacle in being subjected to a minimum weight of 81 maunds.

"Now, you are well aware that aloë-fibre, jute, hemp, flax, when destined for twine or textile manufactures, might be able to bear a second-class rate on account of their higher market value; but, seeing that it is only the cuttings or waste of these materials that are used for paper manufacture, they cannot possibly be of so high a value, and cannot, therefore, bear the same charge. The cuttings or waste should consequently be treated specially and charged a much lower rate."

This can, I venture to think, be done by placing all materials destined for paper manufacture under a distinct head of "paper-making materials" in the goods tariff, and classing the head under Class I. (i.e., 33½ pias per 100 maunds per mile) when the material is loosely packed, and under special class when despatched, pressed or screwed in bales. In neither case need there be any restriction as to minimum weight, and the usual reduction might be allowed when carried over 150 and 300 miles respectively.

#### CHINESE MATTING.

The following remarks from a paper by Dr. Hance, of Hong Kong, published in vol. viii. of the *Journal of Botany, British and Foreign*, are supplementary to the article in the *Journal of the Society of Arts* of May 27th, p. 696. The plant used for sails of native craft, or for covering boxes, and described in the United States Consul's report as an "aquatic grass" or "rush," is a cyperaceous plant, known to botanists as *Lepidosperma mesomata*, Rich. It is recorded as a native of the Indian Archipelago, Australia, and Madagascar. Of the matting made from this plant, Dr. Hance says the natural colour is a pale brown, nor is he aware that it is ever dyed, nor, so far

as he knows, is it ever "exported to foreign except, doubtless, in the form of bed mats &c. residing in Australia and California. It is remarkable that a plant of comparatively high geographical distribution, and in none other of its native localities turned to any account, the raw material for a vast manufacture, and, perhaps, still more strange, that the use should not before have been discovered. As of *Hydrophyllum latifolium*, Griseb., which thousands of tons of a favourite vegetable, it much we may have still to learn, even at the most frequented marts of trade, concerning which many apparently insignificant plants. The attention of the authorities in our possessions Straits of Malacca, and of those of Netherland might be advantageously directed to the cultivation of this plant, and so developing profitable manufacture."

Regarding the floor matting, which for important trade with America that it ranks value about sixth or seventh of all articles foreign countries from Canton, the matting is woven from the culms of *Cyperus Roxb.* It does not seem to be known what the "fa" plant is, from the flowers and seeds yellow dye is prepared, but Dr. Hance is that the "lam-yip," or blue plant, is of the natural order "Acanthaceae."

From a table showing the export of matting from Canton from 1870 to 1877 inclusive, that, next to North America, Hong Kong largest quantity, Great Britain taking the third place as stated above the largest quantity exported in 1872, when 115,220 rolls were

EDWIN.

#### GENERAL NOTES.

**Portable Disinfecter.**—The principle disinfecter, by Mr. Washington Lyon, is the use of steam, under regulated pressure, in a constructed apparatus, in place of dry heat, for destroying all forms of insect life and the low germs, &c. The chief advantages claimed for it are that, while all kinds of wearing apparel, furniture, &c., can be disinfected by its means, no or unmade, the colours of silk, woolen, and cotton are unaffected, papers are uninjured, and all small is avoided. The apparatus is made of an outer casing, with a space between, into which pressure of about 25 lbs. is admitted. The articles to be disinfected are placed in the interior, and the steam, at a pressure of about 20 lbs., is then sent into the interior, which raises the temperature to 258° Fahr., and the process of disinfection is complete. The presence of the steam in the casing prevents the escape of the steam in the chamber. A working disinfecter was exhibited last year at the Sanitary Conference, and it has since been brought to the Public Health, and it has since been brought to the

## L OF THE SOCIETY OF ARTS.

No. 1,496. Vol. XXIX.

FRIDAY, JULY 22, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## ART AND FURNITURE EXHIBITION.

Exhibition of Works of Art Applied to Furniture in connection with the Exhibition of Works of Art at the Royal Albert Hall, is now open. A non-transferable season ticket will be issued to every member of the Society on application to the Secretary. A ticket, to admit two persons, is the subject of the present *Journal*.

## PROCEEDINGS OF THE SOCIETY.

## PLANT LABEL COMMITTEE.

REPORT.—George F. Wilson, F.R.S. (Chairman), J. Bramwell, F.R.S. (Chairman of the Council), Lord Alfred S. Churchill, Rev. H. Harpur, Professor W. T. Thiselton Dyer, F.R.S., Rev. J. G. Nelson, William Sowerby, Rev. J. G. Dod, and Colonel Trevor Clarke. Following is the Report of the Committee, which has been adopted by the Council:—

Under the conditions under which the Society's Silver Medal, together with a £5, which has been placed at their disposal for the purpose by Mr. G. F. Wilson, or the best label for plants. The offer is to obtain a label which is cheap and durable, and may show legibly the name written or printed thereon; the label to be suitable for plants in open border. Considerations will principally govern the award will be made on the recommendation of the committee, which will be approved for the purpose by the Council. Specimens bearing a number or motto, and accompanied by a sealed envelope containing the name of the plant, must be sent in to the Secretary of the Society not later than the 1st May, 1881. The

Council reserve to themselves the right of withholding the medal and prize offered, if, in the opinion of the judges, none of the specimens sent in are deserving."

In answer to this notice, which was first issued in January last, 120 sets of specimen labels were sent in. Some of these are ingenious, but many show ignorance of the conditions to which labels are exposed in open borders, rock-work, &c. There are a great number of applications of glass to labels; some of these specimens were broken even in the transit, showing how unsuitable they are to stand rough usage. Some very useful labels have been sent in, which, though perhaps not absolutely new, are unknown to the generality of cultivators.

The committee are of opinion that none of the labels sent in competition are deserving of the Society's medal, but they have pleasure in expressing their opinion that the following possess many points of merit, and they therefore beg leave to draw the attention of persons interested in the subject to them:—

E. J. Alment, 194, Romford-road, Stratford.—Zinc labels, with galvanised iron wire stems.

J. Pinches, 27, Oxenden-street, S.W.—Zinc labels, with stems of zinc, iron, and oxidised iron. Thomas Johnston, Saw Mills, Renfrew, Scotland.—Labels of teak wood.

J. Wolstenholme and Son, Grimes-street, Mill-street, Ancoats, Manchester.—Holly-wood and box-wood labels.

Rev. H. Ewbank, St. John's, Ryde, Isle of Wight.—Wood labels, with iron wire supports. These are painted white, and a coat of black paint added, which, when wet, is removed where the letters are required, in order to show the white ground beneath.

J. Wood, Woodville, the Spring, Kirkstall, Yorks.—Zinc labels, with galvanised iron wire supports.

Walter J. Todd, 32, Angell-road, Brixton, S.W.—Wood labels, with wire supports.

C. Yates, Mortlake.—Zinc labels of various patterns; ink for writing on same.

S. Mount, Harbledown, Canterbury.—Painted iron labels.

J. C. Turner, Salisbury-road, Blandford.—Zinc labels.

J. Dowdney, 1, Montpelier-villas, West-street, Croydon.—Wood labels, with wire supports.

Rev. C. Wolley Dod.—Iron and wood labels.

There is also an iron label sent in by the Rev. H. N. Ellacombe, for the inspection of the committee, though not in competition, which is well deserving of notice, since it has been in use for more than sixty years in Mr. Ellacombe's garden, and is still in perfectly sound and good condition.

The committee would suggest that the proprietors of the labels sent in should present their specimens to the Council of the Royal Horticultural Society, if that society is willing to accept them, in order that they may form a permanent exhibition of labels. They also recommend that the offer of the prizes should be renewed for the following year, and for the guidance of future competitors they offer a few suggestions.

Wood is probably the cheapest and best material for cheap labels. It is at present liable to the

objections that the part in the ground rots, and the writing on the label becomes illegible. If by some process, such as perfect kyanizing or treatment with paraffin, these objections could be removed, an excellent cheap label would be the result. Such labels, however, would have to be tested in actual use against unprepared labels, before any award upon them could be made. Slate labels, made thick enough not to break, might be useful. Cheap thick glass labels might be useful for the same purpose, if proper means of writing upon them were provided.

H. TRUEMAN WOOD,  
Secretary.

## CANTOR LECTURES.

### WATCH MAKING,

By Edward Rigg, M.A.

#### LECTURE II.—DELIVERED MONDAY, FEB. 14, 1881.

##### *Degree of accuracy required in the ordinary watch—*

*Fourteen years' statistics of the clock and watch trade—Systems of manufacture in this country and abroad—Description of specimens illustrative of the various stages of construction—Comparison of the several systems.—Suggestions.*

The latter portion of the last lecture was devoted to the consideration of certain points connected with the manufacture and adjustment of high-class watches. I endeavoured to show that, although it may be quite possible to produce a going-barrel watch that shall indicate strictly accurate time at any period through the 24 hours, the care required in the adjustment of so perfect a timekeeper is far greater than when a fusee is employed, for the variation in the force of the best going-barrel springs will cause the arc of vibration to fall off to the extent of about 100°, an amount which represents a very severe tax on the isochronism of the balance-spring. As the delicacy of the instrument may be considered to be in proportion to the care required in its adjustment, it is difficult to see what valid reason can be urged against the fusee in such watches as we are considering. By securing a motive force that is approximately uniform, it very materially diminishes the labour involved in the production of a timekeeper that can be relied on to be accurate throughout the whole day, and, therefore, may be said to actually reduce the cost of manufacture of the best English watch, at the same time increasing its reliability.

But, after all, it is not every buyer that requires such an exact instrument; and the table given at the end of the last lecture seems to show that, for ordinary use, the going-barrel watch has been the subject of very marked advance in recent years. Formerly, when the English and Swiss makers had the entire trade of the world practically in their own hands, and while the English fusee watch was celebrated as a high-class timekeeper, the Swiss going-barrel had complete control of the cheaper markets. But since about the middle of the present century the production of France has very largely increased, and more recently American manufacturers have appeared as competitors, both in their own country and in Europe. This rapid increase in total production, and the improvements in the going-barrel,

point to the conclusion that English makers should examine most minutely into their system of working, carefully study the merits of every suggested improvement, and themselves take the watch in hand, investigating any weak points in its design or system of manufacture.

That there is urgent need for such exertions at the present day, especially in regard to the medium and cheaper class of watch, is, I believe, generally admitted, and I have been at some pains to collect such statistical information as might enable us to see how far the growth of foreign competition during recent years is real: the returns must show that the English watch trade is, in a sense, in a more hopeful condition than some would have us believe, notwithstanding that it cannot be said to exhibit any marked signs of growth.

They cover a period of fourteen years, namely from 1867 to 1880, and are comprised in six tables. Some of the information has been already published, but only a very small proportion of that given, and never in a collected form. Thus certain hall-marking returns are annually made public, many of the figures in Table VI. are new, have been expressly supplied to me by the authorities of the Assay Offices at Birmingham, Chester, London, to whom I would here express my thanks. The fulness of the returns of imports and exports as compared with those hitherto accessible, may be gathered from the fact that these latter have consisted only of (1) total annual imports of clocks in number and value, and (2) total annual imports of watches in sterling value. These constitute columns 14, 15, and 20 of Table I. Exports have been entirely ignored, as also the details regard to imports. I should mention that the oversight has evidently arisen from the fact that only the Monthly Statements and Annual Abstract of the trade of the United Kingdom, published by the Board of Trade, have been consulted; whereas it is only the "Annual Statement" of the Department that contains the full information.

It would be impossible, within moderate space, to discuss these returns fully; an attentive examination of the figures will be well repaid, as it will bring to light many points of interest, the import of which one individual may be in a better position to appreciate than another. I propose, however, to add a few notes to each table, drawing attention to its most prominent features.

*Table I.*—The superior quality of the clocks imported from France is made very evident by dividing the value (which, I may here mention means "declared value") by the number in each country. Thus, taking the year 1879—

A clock from Belgium*	is valued at	£0.43
"	France	" 3.27
"	Germany	" 1.28
"	Holland	" 0.27
"	United States	" 0.56

Our imports of these cheaper clocks are increasing at a rapid pace, whereas those from France remain stationary. This fact is brought into prominence by the column headed "mean price." The numbers of clocks from the United States and Holland are nearly identical.

\* It should be noticed that where Belgium is mentioned in regard to imports, it may taken to mean Swiss manufactures shipped at Belgian ports. Similarly, Holland exports the manufactures of the Black Forest.

In regard to imported watches, there are several noticeable facts. Since 1870, the beginning of the Franco-German war, Swiss watches have come to this country by way of Belgium instead of through France, indeed, the tariffs imposed by the French Government are so prohibitive, that the great majority of the French watches pass into Switzerland, and are then exported to England by the same route. Under "Other Countries," in 1880 are included watches to the value of £2,115 from Holland, and £2,197 from the Channel Islands.

The American watch trade does not figure in the returns, for imports from "Other Countries" only amount to about £5,000 per annum. 1876 was the only year in which America was specified, when the amount recorded was £4,272 (and this I have included with the amount given for "Other Countries"). The relatively large figure in 1879 comprises £13,933 from Holland; and thus the returns, full as they are, must be regarded as deficient in this important particular. The omission appeared to me to be so serious that I consulted Messrs. Robbins and Appleton with a view to its explanation, and they have obligingly given me, for publication, the number and value of their imports into this country during last year. The "movements" imports numbered 24,330, and the approximate value was £40,000; the reason for the omission from the official returns appears to be that the watches are all without cases, and are therefore classed at the Custom-house as "watch materials." These figures will enable us to apply an approximate correction to the total imports for the previous years.

The section headed "Net Imports" is deduced from the total imports by deducting the exports of foreign produce shown in Table IV.; the figures thus obtained, together with the American watches imported, must be taken to represent the annual home consumption of foreign-made clocks and watches. They show a rapid growth in the number of clocks, and a somewhat irregular but distinct growth in the value of watches; the net imports during the year 1880 are, however, in both cases, somewhat below those of the year that immediately precedes it.

Table II.—The first column of Table IV. gives the gross annual value of the exports of home produce, classed as "Clocks, Watches, and parts thereof." I thought it advisable to include all the information supplied by the Government Returns, and have therefore prepared this Table II. It is, however, in a sense unsatisfactory, owing to the fact that in many instances different countries were specified from year to year as importing the manufactures of Great Britain; but since 1871 there has been a greater degree of uniformity, although the subdivision is less complete; nevertheless, the table is in a high degree interesting, as showing who are our best customers, but it does not call for much special remark. The £20,038 sent to "Other Countries" in 1881 includes £2,187 in exports to Germany.

The statistics prior to 1870 are singularly complete, as clocks and watches are given separately both by number and value. Comparing the line of totals at the bottom of the table with the first column in Table IV., it appears that about 60 per cent. of the exports are watches, the mean price of which fell gradually from £6.76 in 1867 to £4.76

## II.—DISTRIBUTION OF HOME PRODUCE EXPORTED.

NOTE.—Since 1870, the Exports of Home Produce are given only in Sterling Value under the heading "Clocks, Watches, and parts thereof."

a mean price of English clocks exported out the same proportion. Our best Australia; Belgium generally comes the large amount of our exports to the be will be a matter of surprise to many. I.—This gives information similar to ed in Table II, but in regard to foreign orted from this country. The returns e such details in regard to foreign cept in one or two isolated cases, which ord in the notes to Table IV. These w that our exports of foreign clocks tedily increasing for many years past, there was an extraordinary expansion, representing both number and value, y double those of the preceding year.

One feature of this Table III. to which I would draw attention, is the large export of foreign clocks to Sweden and Norway from this country; it is certainly unexpected. In the exports to "Other Countries" in 1879 are included 1,049 foreign clocks (valued at £4,920) sent to France, and 14,079 (valued at £7,066) sent to China. Exports during 1880 to countries not provided for in the Table (which I have included under "Other Countries") are:—

	No.	Value.
China .....	21,878	£11,810
France .....	1,613	6,162
Hong Kong..	24,527	11,241
Japan .....	19,329	8,125

—Table IV., giving an annual summary of exports, is convenient for reference, and is an index of the state of the English trade statistics afford. There is a decided rise in the column headed "Home Produce," indeed the last figure, that for 1880, is £1,512 above the mean of the previous years. The exports of foreign produce may, from a commercial point of view, be regarded as forming part of the home trade; they also show a decided rise; we are therefore safe in concluding that the English trade is certainly not in such a depressed state as some would have us believe, and 1880 stands out as the one in which a far greater amount of foreign trade was done than in any previous year.

The returns add the following particulars, which I will give for the sake of completeness, although they are of no special moment:—

*Foreign Watches Exported.*

1871.	To the United States ....	£47,606
	„ Other countries .....	12,294
1876.	„ Belgium .....	17,169
	„ Other countries .....	2,228
1877.	„ Belgium .....	21,731
	„ Other countries .....	2,312
1878.	„ Belgium .....	26,612
	„ Other countries .....	3,988
1879.	„ Belgium .....	21,302
	„ Other countries .....	9,043
1880.	„ Belgium .....	26,274
	„ Other countries .....	5,743

*Table V.*—As, prior to 1870, numbers as well as value were always given in regard both to imports and exports, I have added this table, which consists mainly of “Mean Prices” calculated from these returns. The mean price of both clocks and watches of home manufacture exported fell regularly as already mentioned; and full details are given of the manner in which other prices varied, as well as all particulars of the numbers of the several articles imported and exported.

The figures in regard to chronometers exported cannot be taken as in any way an index of the amount of our foreign trade in that branch, for many vessels obtain their supply when in an English port, and this would naturally not be included as an “export.”

The last column of the table gives the average mean prices during the four years under consideration, and, taken in conjunction with the preceding tables, they constitute the sole means at our disposal for ascertaining approximate numbers in recent years. Thus, taking £5.41 as the average price of an exported English watch, and remembering the fact, already mentioned in speaking of Table II., that about 60 per cent. of the total exports are watches, it appears from the second column of Table IV. that, for example, in 1880, we exported about £100,000 in English watches, and that their number was approximately  $\frac{100,000}{5.41}$  or 18,480. The

mean price of an imported foreign watch being taken to be £1.60, it appears from the last column but two of Table I., that in the same year we imported for home consumption  $\frac{401,646}{1.6}$  or 251,030

foreign watches, to which we may probably add about 20,000 of American manufacture that are not included in the returns. Now, the last census showed that there were 23,766 men and 749 women engaged in the clock and watch trade in the United Kingdom, or a total of 24,515. Thus it appears that we actually did not export one watch per head of the watchmaking population, and imported about ten. It would perhaps have been fairer to compare the population with the returns for 1871, the year of the Census. The export of home watches was then about  $\frac{116,000}{5.41}$  or 21,250, and the net imports of foreign

watches  $\frac{499,514}{1.6} = 255,970$ , and the proportion therefore is even worse (as 1 is to 12),

*Table VI.*—This table gives the returns of watch cases hall-marked at the several Assay

Offices; numbers that have hitherto been as an index of the state of trade in this. But a little consideration will suffice to show they are subject to much uncertainty, and are fallacious when used for such a purpose. Many cases are imported in order to re-hall-mark, and subsequently enclose for works. Their number is very uncertain, and will be seen from the information supplied by the Chester Assay Office authorities that since 1876, when cases appear to have been first sent to England for this purpose, they have averaged about 13,000 per annum at Chester, and not more than 7.5 per cent. have been re-hall-marked. The latter fact seems to point to the conclusion that the gold cases marked would afford a fair index of our trade than the total number, but, if accepted, the returns for the last few years certainly indicate a steady fall in the number. At the same time it is well to note that the returns from the Chester returns alone, the silver cases of home manufacture show a large increase, and a gradual decline of the number of foreign cases marked at Chester justifies the conclusion that the diminution of total numbers is not entirely borne by the foreign trade. Further uncertainty is occasioned by the fact that many English cases are fitted with foreign movements, and we have no means of ascertaining how their number varies from year to year.

And there is yet another source of error in these hall-marking returns as an index of the watch trade. The Birmingham Office cases by gross weight, and the number calculated on the assumption that each case weighs about 1½ oz.; but this is obviously liable to considerable error, more especially if many cases are included, as they never reach the average weight.

There is one fact, then, which the returns have been able to collect bring into prominence; it is the utter impossibility of drawing any reliable conclusions as to the English trade from these returns of the Assay Offices. The year 1879, affords a notable instance of this fact. In comparison with the number of cases marked at Goldsmiths' in that year, with those of years immediately preceding it, the *Horological Journal*, in 1880, observed:—“Short of absolute certainty, the English watch manufacture certainly is at a low point as possible during the last few years passed.” Now, in the light of the returns, what are the facts? The number of cases marked at Goldsmiths' in 1879 (Table I.) were £2,500 above the average of any previous nine years, and the export of cases (Table IV.) were £1,600 above the average of the same period.

The returns of the total export trade exclusive of foreign clocks and watches, given in Table IV., afford still more conclusive evidence of the relative prosperity of 1879. They reach a total of £223,815, considerably in excess of any previous year, except 1871, when the exports were abnormally expanded by £47,606 watches sent to America. And the exports of that year are even exceeded by those of 1880, which shows a gross increase of £32,515 over 1879, owing to the fact that the foreign clocks re-exported were largely in excess, although there is a small increase in home produce.

But these returns prove another point which is less satisfactory. While they show that our export trade in 1879 and 1880 were above the average of preceding years, they also show that the rapidly increasing home demand is, at least to a very large extent, supplied by foreign makers, so that our credit abroad actually appears to be better than in this country.

The cause of the difference of £1.26 between the prices of imported and exported foreign watches is not clear; it is, however, probably in the main, due to the fact I have already mentioned, that many of the latter come to this country to be cased; in instituting a comparison, therefore, with those of home manufacture, it would be fairer to take the two export prices rather than the import and export.

It is unfortunate that more recent details in regard to the mean price are not accessible, but, accepting those already given for 1867-1870, is it fair to conclude that the average English watch exported is so much superior to the average foreign watch, as to justify so marked a difference in price as there is between £5.41 and £2.86? Few will, I think, be prepared to maintain that it is not open to question, and however hopeful statistics may be, the trade cannot be said to be in a satisfactory condition until either such a difference is justified, or the price is reduced.

In considering such a subject, there are many circumstances to be taken into account. High quality must always depend largely on the education of the workman, and the honesty with which he does his work; moderate price must be aimed at by systematising the manufacture, and will always be in a great measure influenced by the amount of production.

(To be continued.)

## MISCELLANEOUS.

### CITY AND GUILDS OF LONDON INSTITUTE.

The first stone of the Central Institution of the City and Guilds of London Institute for the Advancement of Technical Education, was laid on Monday, 18th inst., by his Royal Highness the Prince of Wales, who was accompanied by the Princess of Wales. The building will have a piece of land in the Exhibition-road, South Kensington, between the Indian Museum and the Albert Hall, granted to the institute at a nominal rent by the Commissioners of the Exhibition of 1881.

The Lord Chancellor said—May it please your Royal Highness, I have to express, on behalf of the council of the institute of which I have the honour to be chairman, our gratification at your presence here to-day to lay the foundation stone of the Central Institution of the City and Guilds of London Institute for the Advancement of Technical Education, and, at the same time, to offer our grateful thanks to her Royal Highness the Princess of Wales for the interest which she has been graciously pleased to manifest in our work by accompanying your Royal Highness on this occasion. The council and the governors of the institute have heard with unmixed satisfaction that your Royal Highness has graciously consented to become the President of this association, the objects of which are the improvement of the industrial and commercial pursuits of this country, by

affording facilities to apprentices, foremen, men, works, and manufacturers, to become practically acquainted with the principles of science and its application to industrial operations. The inst. grown up by the united efforts of a few of the guilds of London, which, having combined purpose of assisting in the advancement of education, obtained later on the help of corporation of London and of other livery or 22 of which, including nine out of the guilds, are represented on the council institute, and jointly contributed nearly annually to its funds. At first, the effort association were confined to the encourage technical education in schools and colleges in and elsewhere; but latterly the institute enabled to establish and organise schools of it technical instruction, and also to assist in the ment of technical education in a large number in the United Kingdom. This institution was established as a rival to any other existing learning; least of all to the excellent schools in this neighbourhood, which for some years, been the means of offering to hundreds of young women a knowledge of the principles of and art. The aim of this institution was to supplement the teaching of those schools, by instruction in the practical application of and art to the trades and industries of the and by cultivating and endeavouring to inventive genius. As President of the Royal mission for the Exhibition of 1881 this inst. already greatly indebted to your Royal High the other members of the Commission, for this a nominal rental of the valuable plot of ground, this institution is to be erected. The institute fully sensible of its obligations to her Majesty's missioners, without whose kindly assistance the of this college might possibly have been delayed gives me great pleasure to be enabled to add it seemed fit to her Majesty to recognise on this the eminent services of Mr. Bramwell, the fatigable chairman of the executive committee the institution, by signifying her Majesty's intention of conferring upon that gentleman the honour of knighthood. It is anticipated cost of this building, when fully equipped apparatus and appliances needful for technical instruction, will not fall far short of £75,000. sum £31,000 has been already subscribed by worshipping companies of Fishmongers, Grocers, Clothworkers, and Cordwainers; the great Drapers' Company having been appropriate Finsbury College; and it is expected that about will be saved from the annual income of the during the building of this college. The therefore, after paying the amount which is have at their disposal only an estimated sum £55,000, and they look to the liberality of the Companies, both of those who have and of those who have not as yet subscribed to the fund institute, to make good the balance of £20,000 the building of this college may be completed once and as a whole, in strict accordance plans. It is confidently hoped that the presence Royal Highness and of her Royal Highness the Princess of Wales here to-day, sanctioning and approving objects for which this institute has been formed for the promotion and further development of this central institution is to be erected, and proof of her Majesty's gracious approval will be enabled to announce, will stimulate the Guilds of London liberally to bestow their aid in the work which they have so wisely and so inaugurated, so that this important edifice, stone of which is to be now so auspiciously laid, be worthily established and adequately adorned.

is Royal Highness the Prince of Wales then said,—Lord Chancellor, my Lords, Ladies, and Gentlemen,—I thank you for your address, and beg leave to say to you that it gives me much satisfaction to attend to-day, to lay the foundation stone of an institution which gives such forcible expression to one of the most ardent needs in the education of persons who are used to take part in the productive history of this country. Hitherto English teaching has chiefly relied on training the intellectual faculties, so as to adapt men to any occupation of life to which they may be called, and this general discipline of mind has, on the whole, been found sufficient, until of late times; but during the last 30 years, the commerce of other nations, even in manufactures which once were exclusively carried on in this kingdom has been swayed. The great progress that has been made in the use of locomotion, as well as in the application of steam to the purposes of life, has distributed the raw materials of industry all over the world, and has economised labour in their conversion to objects of utility. In nations which did not possess in such abundance as Britain coal, the source of power, and iron, the basis of strength, compensated for the want of raw materials by the technical education of their industrial men, and this country has, therefore, seen manufactures springing up everywhere, guided by the skill and intelligence thus created. Both in Europe and America, technical colleges for teaching, not the theory, but the principles of science and art involved in particular industries, had been organised in all the great centres of industry. England is now thoroughly conscious of the necessity for supplementing her educational system by colleges of a like nature. Let me remind you that the realisation of this idea was one of the most valued objects which my lamented father had in view at the Exhibition of 1851, he recognized the need of technical education in the future, and he foresaw how suit it would be in London to find space for such various and colleges as those which now surround the one on which we stand. It is, therefore, to me a great pleasure that the Commissioners of the Exhibition, of which I am the President, have been able to contribute to your present important undertaking, by giving to you the ground upon which the art college is to be erected, with a sufficient reserve to ensure its future development. Allow me, in addition, to express the great satisfaction which I derive in seeing the ancient guilds of the City of London so warmly co-operating in the advancement of technical instruction. I am aware that several of them for some time past in various ways separately encouraged the study of science and art in the metropolis, as well as in the provinces; and it is a noble thing on their part when they join together to establish this institute with the view of making still greater more systematic endeavours for the promotion of technical education. By consenting at request to become the president of this institute I think it may be in my power to benefit the good work, that our joint exertions, aided, I trust, by the liberal liberality of the City and Guilds of London, may well be an example to the rest of the country to the intelligence of industrial communities, so that, in the increasing competition of the world, England retain her proud pre-eminence as a manufacturing nation.

Mr. F. J. Bramwell then presented to his Royal Highness a medal, which had been struck at the Royal Mint commemorating the laying of the stone, bearing on the obverse the shields of all the contributing Companies, and on the other side a record of the event to place that day.

Mr. Sydney H. Waterhouse handed to his Royal Highness who placed it in a cavity in the stone, a glass and a case containing the smaller weights of the country,

coins, and a copy of *The Times*, *Nature*, and the *City Press*; also a medal and a document recording the laying of the stone.

Mr. Norman Watney having presented to his Royal Highness a handsome silver and ivory trowel, the column of polished granite was then lowered into its proper position.

The Prince of Wales then said,—In the name of the Father, the Son, and the Holy Ghost, I declare this stone to be duly laid.

### THE MINT.

The eleventh annual report of the Deputy-Master of the Mint has lately been issued, and the following is an abstract of its contents:—

The demand for bronze coin having been far below the average, it has not been necessary to provide for the execution of any part of the coinage by contract during the year, but the Department has been fully occupied in meeting the demand for gold and silver coin, and in supplying three unimportant coinages to colonies. Three other colonial coinages, of larger amounts, which pressure of work did not permit the Mint to undertake, were executed by contract under the supervision of the Department. The requirements of the Bank of England were met by a coinage of rather more than £4,000,000 of gold, or about £1,000,000 less than the average, but the coinage of silver, which has exceeded £744,000, has been larger than that of any year since 1874. The coinage of bronze, on the other hand, has barely exceeded £19,000, as against an average of £42,600 in the preceding five years.

The coins struck during the year 1880 were of twenty-three different denominations. The total number of pieces struck at the Mint was 26,870,533, as against 30,050,311 in 1879, and their value, real or nominal, £4,926,255 15s. 8d. The total number of British coins struck during the year was 26,812,033, and their value was as follows:—Gold, £4,154,804 10s.; silver, £744,820 8s. 11d.; bronze, £19,471 15s. 9d.

#### GOLD COINAGE.

The coinage of gold commenced in December, 1879, and was concluded in July, 1880. The amount coined in 1879 was insignificant, but during the first six months of 1880, a sum of rather more than £4,150,000 was delivered to the Bank of England in sovereigns and half-sovereigns, and the total value of the coinage was brought up to £4,185,120. This is the largest gold coinage executed since 1876, when the amount issued in the year was £4,700,000. During the intervening period of three years, owing to the general depression of trade, the annual average demand for gold coin from the Mint has been but little more than £1,000,000, the importations of sovereigns issued by the Sydney and Melbourne Mints having each year been sufficient to make up the quantity of new coin required by the Bank of England. During the year 1880 the amount of Australian gold coin imported was £2,377,000, as against the following amounts in the preceding five years:—

1875	£2,736,000
1876	2,075,000
1877	3,740,000
1878	2,773,000
1879	1,817,000

#### SILVER COINAGE.

The silver coinage of the year, as already stated, was considerably above the average. The amount of coin struck was £744,820, as against £567,125 in 1879, and £514,428 in 1878, and the amount issued £709,000. The issues consisted of £190,700 sent to the Bank of England, £123,000 to the Bank of Ireland, £73,500 to Scotch banks, and £308,800 to colonies; £13,350 shipped in aid of Treasury chests abroad, and £500 in threepences supplied direct to banks and private persons. As in

former years, applicants for small sums in threepences were referred to London banks which had intimated that they held a stock in excess of their own requirements, and the amount sold to individuals, therefore, was inconsiderable; but the total amount issued, nevertheless, reached £28,050. This amount, though less than the issues of 1879 and 1878, which were £37,220 and £30,428 respectively, shows that the demand for threepences is still very large. It may be mentioned in this place that fourpences, none of which have been coined since 1856, continue to be withdrawn in considerable quantities, and will shortly no doubt almost entirely disappear from circulation. The nominal value of the fourpences withdrawn during the past year was about £4,000, and in 1879 was £3,800, so that the number of these pieces in circulation has been reduced in two years by not less than 466,000.

The half-crowns issued during the year have been of the nominal value of £164,920, and the total amount of these coins issued since 1874, when their coinage was resumed, has been £992,070.

There has been a decided increase in the demand for silver coin in England and Wales during the past year. In the latter part of 1878, and during the greater part of 1879, owing to the general contraction of trade and the depression of agriculture, large quantities of coin were received back by the Bank from the public, but, in 1880, the issues again largely exceeded the amounts received, and the silver currency, therefore, may be considered to have resumed its normal condition. The amount of worn silver coin withdrawn from circulation, £350,000, continues to be large, and shows that the renewal of the coinage progresses satisfactorily.

In Scotland and Ireland also, the demand for silver coin has been considerable.

Notwithstanding the large issues of 1879, which amounted to £298,470, the amount of new coin shipped to the colonies has during the past year shown no signs of diminution. The demand for silver coin throughout the colonies in which the Imperial coinage is current has been greatly stimulated by the arrangements made at the beginning of 1879, under which the Mint was authorised by their Lordships to pay all expenses connected with the carriage of new silver and bronze coin to, and of worn silver coin from, British dependencies.

In connection with the withdrawal of worn silver coin from circulation, the "Loss by Exchange" for the year 1880 was £58,696, as against £54,702 in 1879, although the amount of coin sent in for re-coinage in 1880 was only £485,015, as against £495,065 in the previous year.

The average market price at which standard silver has been purchased for coinage during the year 1880 has been 52½d. per ounce, so that, as the rate at which silver coin is issued by the Mint is 66d. per ounce, the seigniorage accruing to the State has been at the rate of 13½d. per ounce, or 26½ per cent.

#### BROWN COINAGE.

The bronze coinage of the year, as already mentioned, has been comparatively small, having only amounted to £19,400, and the issues, though exceeding this sum by £9,000, have still fallen short of those 1879 by no less than £10,000. It would appear, therefore, that the very large issues made since the first introduction of the bronze coinage in 1860, which amounted up to the end of last year to £1,475,608, have at length begun to affect the demand.

Of the amount issued in 1880, £19,840 consisted of pence, £6,058 of half-pence, and £2,772 of farthings, as against issues in 1879 of £28,050 in pence, £7,735 in half-pence, and £3,185 in farthings. The demand for each denomination of coin, therefore, has sensibly diminished.

The bronze metal purchased for coinage during the year amounted, as in 1879, to 100 tons, in bars ready for coinage.

The result of the general account of the expenses and receipts of the past year, as in the two previous

years, has been a loss, but it is satisfactory to see that whereas the excess of expenses over receipts in 1878, £81,543, and in 1879, £27,856, it was reduced to £7,858. It might have been hoped that as the purchases of silver bullion for coinage are generally the principal source of profit, as was the case in 1880 as in 1879, the receipts might more have exceeded the expenditure, but on the withdrawal from circulation of worn silver its nominal value was again very large, and so counter-balanced the profit on the conversion of bullion into new coin, while the profit on the coinage was slightly less than in 1879, and the on a gold coinage of £4,000,000, which came in of payment during the year, formed a further loss. The transactions of the Mint, however, the nine years which have elapsed since a "Loss Account" was first compiled in its present form still show an annual profit of £17,920; and it is expected that, as trade revives, the causes which favourably affect these transactions will continue.

#### COUNTERFEIT COINAGE.

The only counterfeit of special interest brought to the notice of the Mint during the past year was a spurious sovereign of platinum found in New Sydney, and forwarded by the Deputy-Master of the Sydney Mint, with a report of Dr. Leishman, that branch. Platinum counterfeits are not new, but the specimen in question bore traces of an impression, and it appeared probable at first a genuine Russian platinum coin had been altered and gilt. After careful examination, however, it was found that on the obverse of the counterfeit the effigy of George IV. was clearly traceable, the figure being also visible. It became evident, then, that the spurious sovereign had originally been made of the Spanish gold coin.

#### OBITUARY.

Lord Hatherley, F.R.S.—Lord Hatherley's death, at the age of 80, took place on the 11th of his house in Great George-street, Westminster, member of the Society from 1859, in which year (then Vice-Chancellor Sir William Page) was elected a Vice-President of the Society for the time. In 1860 he took the chair, when a "Science in our Courts of Law," was read by Angus Smith, and from that time till 1860, finally retired from the Council, he took an active part in the work of the Council and the Committee of the Society. In recent years he was several times asked again to serve on the Council, but he declined on the ground that his increasing years brought no leisure, brought a diminished amount of work, and he was always reluctant to allow to appear when he was unable to take an active part. But, though he had thus retired from a vice to the Society, he was always ready to lend counsel and advice when it was required, and on occasions the Society's interests thus profited. The full accounts of Lord Hatherley's career, which have appeared in the daily and weekly papers, render it unnecessary to give any detail in this Journal; nor would it be becoming to more than allude to the reverence and affection he was held by all who knew him. It may be said to say that he at all times took a keen interest in literary and in scientific progress. He was an author, his principal work being "The Old Testament," published in 1867. As far as he was elected a Fellow of the Royal Society, he has several times served on the Council.

#### LECTURE LECTURES.

##### WATCHMAKING,

by Edward Rigg, M.A.

##### LECTURE II.—(Continued.)

As I shall endeavour to explain  
systems of manufacture in this  
tries, but would first say a few  
design of the watch. This is a  
only practical watchmakers can  
there certainly are faults in many  
that even a non-technical observer  
ve noticed. They are most marked  
d a full-plate watch, a watch, that  
several moving parts are held in  
o circular plates, the balance  
sition external to the rest of the  
icular form has come to be known  
world as the "English watch," and  
h only one essential change, namely,  
e escapement, for the last 200 years.  
It is, at first sight, a matter of  
re consider the changes that have  
all the sciences and the mechanical  
ece of mechanism, important as it  
of society, should have so long  
ary, or nearly so. This fact has  
ferred to in the first lecture, and  
en there given why we should not  
such radical change in its design.  
so much appear to be occasion for  
new escapements, &c., as for the  
simplifying of the watch as it

already exists; and, above all, there is the need  
of replacing vague rules of thumb by definite  
principles of construction, and of taking advantage  
to the utmost limit, in practice, of the aid which  
theory has to offer.

Where is the necessity for making the English  
watch so much thicker than others? Why are we  
obliged to have a watch that involves opening the  
face to set to time? And why does a common Swiss  
or French watch often present a far more attrac-  
tive external appearance than many of those of  
English make at twice the price? The faults in  
the design of the mechanism itself are quite as  
numerous, but I will not now stay to enumerate  
them, and to those who care to inquire into them  
would commend a suggestive article by Mr.  
Glasgow,\* published only last year in the  
*Horological Journal*.

The criticisms that have to be met apply  
in the main to full-plate watches. This form has  
been gradually abandoned, in the case of high-  
class work, in favour of the half and three-quarter-  
plate, in which a portion of the top-plate is cut  
away, so that the balance may be in the same  
plane with or even below it, thus diminishing the  
thickness by about an eighth of an inch. The  
change was somewhat distasteful to the public at  
first, and there seems still to be an extraordinary  
amount of indirect opposition to it on the part of  
many workmen connected with the trade. Thus  
an escapement to a three-quarter-plate watch  
generally costs twice as much as for a full-plate  
watch, and a similar distinction is made in several  
other stages. But there seems no sufficient reason for  
so great a difference. It is, doubtless, in part owing  
to the fact that, as a rule, the three-quarter-plate  
watch is of a better quality, and work on it is,  
therefore, naturally more highly paid; but there  
appears to be no reason, unless public prejudice  
be considered one, why all qualities, even the  
lowest, should not be of similar design. Indeed,  
in Switzerland, the very cheapest watch manu-  
factured is on the three-quarter-plate model.

The manufacture of a watch involves a very  
great number of distinct operations, each of which  
requires considerable knowledge and skill on the  
part of the workman.

During the sixteenth and seventeenth centuries,  
when pocket timekeepers were first introduced, the  
watchmaker, as a rule, himself made all the parts  
of both watch and case, employing only a few  
simple tools. But since that period the work has  
become gradually more and more subdivided, and  
each workman, by constantly confining himself to  
the making of one special object, is enabled, as in  
all handicraft, to make it both more rapidly and  
more accurately. At the same time, the simple  
tools of the early makers have been more or less  
elaborated, so as to abridge and facilitate the work—  
at times, indeed, to such an extent that the skilled  
workman himself is rendered unnecessary.

These latter machines are of comparatively  
recent introduction, and the collection of tools  
which I hope to exhibit on Monday next, show  
how much of the work of an ordinary watchmaker  
depends on his manual skill. But in recent years  
machine-tools have come more and more into use,  
and these have naturally tended towards the in-

\* *Horological Journal* (1880), xxii., p. 92.

production of a factory system, in place of what was essentially a home manufacture.

Thus three systems are now possible for the production of watches on a large scale:—

(1.) Each workman, becoming an adept at one or more special trades, remaining independent, and working for a number of employers.

(2.) Workmen in all the trades being collected together in one large factory, which is thus in a condition to produce finished watches from the rough metal.

(3.) A combination of these two systems.

I propose to consider these separately, and will endeavour to point out some of their relative merits, as bearing on the English watch-making industry. The first is that mainly practised in England, Switzerland, and France. A frame, containing the barrel, fusee (if any), centre, third and fourth wheels, all with their teeth cut and pinions attached, and certain other portions in the rough, constituting a *movement*, is manufactured, say at Prescott, in Lancashire, and delivered to the Clerkenwell or Coventry manufacturer. After numbering it, he sends it, or the requisite portion, in succession, to the dial-maker, case-maker, escapement-maker, finisher, gilder, fusee-cutter, jeweller, &c., and, finally, to the examiner, who adjusts the balance-spring, and regulates the watch, returning it to the manufacturer. In all, at least 40 artificers aid in the production of a lever watch, but of these the most responsible is the finisher, whose duty it is to turn the pivots, preparing everything for the gilder, determining the positions of all the wheels, so that the train runs freely, drilling all pivot-holes, except those of the escapement, &c., but he does not, as his name would suggest, finish the watch. And the examiner is called upon to find out any faults in his predecessor's work, see that they are corrected, fix the balance-spring in position, and approximately regulate the watch.

It would be both tedious and unprofitable to attempt to pass in review the various stages through which a watch passes; but as the kindness of several manufacturers, both English and foreign, has supplied me with a number of movements, &c., mainly with a view to show the extent to which machinery is employed in their production on different systems, I think we may with advantage devote some time to their consideration and comparison. But we shall be more in a position to do so after the three systems of manufacture mentioned above have been passed in review.

Now, the high-class English watch furnishes a sufficient proof that splendid work can be produced under the first-named system, and it may be doubted whether, for such work, any better could be devised; for many of the operations seem to be exceedingly trivial, and it is improbable that any single manufacturer should have so large a trade as to enable him to retain the services of so many specially skilled operatives. At the same time, it should be observed that this cannot be regarded as an economical system. Babbage, in his "Economy of Manufactures," lays it down that the division of labour cannot be successfully practised unless there exist a great demand for its produce, and, considering as we are at present doing only the high-class watch, there can hardly be said to be such a demand. But the system is strongly recommended by the

fact that it enables a number of manufacturers to avail themselves of the most highly trained workmen, when these are remarkably few in number, and would not otherwise obtain sufficient employment.

While other points must take precedence of economy in the case of high-class work, it is of primary importance with regard to cheap watches. Foreign watches of good quality are now sold in this country at such low rates, that an English-made watch, if of medium quality, must be sold at a moderate price also, or it will most assuredly, in time, be driven out of the home market, as it already has been to a great extent from abroad. The minutest economies must, then, be practised at every stage of its manufacture, and all parts that are not essential to fair time-keeping must be avoided.

I feel considerable diffidence in saying anything on this question, as it is so essentially one for practical watchmakers, but I will briefly refer to one or two points for which the public are in a great measure responsible. If the buyers of watches—who, unfortunately, too often know nothing whatever of their internal arrangements—would content themselves with the selection of a suitable case, leaving it to the watchmaker to decide on the nature of the movement, a great step would be gained. As long as there is a demand for cheap watches provided with fusee, compensation balance, &c., plate, and the like, such watches will be made. The general introduction of keyless work has done much to prejudice the ordinary English trade, its very manifest advantages have gone far to override the popular notion in favour of wind to the left, a feature by which the least initiated could distinguish our own from foreign movements. Indeed, so deep-rooted is this distinction in some districts, that the introduction of English going-barrel watches has been much impeded; certain manufacturers have been induced to do it by providing a separate axis for the wind square, which carries a steel wheel engaging a similar wheel on the barrel arbor; the wind is thus to the left, and the absence of a fusee is not noticed.

This is only one example of the way in which prejudice interferes with the advance of the industry. But it is perhaps the most important, as it involves the question whether the fusee shall or shall not be retained by English watchmakers. If the prejudice were done away with, the fusee could be regarded from the single point of view of merits and defects, and it need not, as is at present the case, be retained partly as a question of policy. In the last lecture I endeavoured to explain what are the real advantages of the fusee system, and why it should form a part in high-class compensated and adjusted watches properly made, with a chain of sufficient thickness. It need not be a source of weakness, but frequent breaking of chains, and the consequent difficulty of its repair by ordinary workmen, have done much to bring it into disrepute for cheap watches. And, after all, is its retention so much desired in them? We have seen that its principal virtue consists in facilitating the adjustment of isochronism and positions. But it cannot be that such watches as are here referred to

or position and isochronism, and experience that they may be made to keep very time from day to day, if wound up

without any such adjustment, as well as the going-barrel as with a fusee and this we have abundant evidence in the of very many cheap French, Swiss, and as well as in English going-barrel watches. type of construction, moreover, lends more to the application of machinery manufacture, involves less risk of breakage by careless workmen, and can be keyless work at far less expense. There can be no real reason for the retention of the fusee in the class of watch we are considering. I believe that, if it were not for the just referred to, manufacturers would readily and willingly to abandon it.

The new system of manufacture referred to is a system, namely, of collecting workmen of allied trades in one large factory, which is in a position to produce finished watches of every kind of metal, has reached its most development in America. There are many such factories on the Continent and in this country, but America are on by far the largest scale; they are, I believe, the only makers that manufacture every part of a watch on the premises. And it will at once be evident that only producers could afford to do so, as many though involving special skill, can be done with great rapidity, and thus workmen employed would be kept idle, unless a proportionately increased number were engaged on the operations.

The Rotherham Watch Factory gives employment to 40 operatives, half of each sex, and produces 100 finished watches a day, so that it overcomes the difficulty above referred to. It has distinct departments, and every branch including, for example, hand, mainspring, making is stated to be executed on the premises. Machinery is used to a very great extent, giving a high degree of uniformity in the results. It greatly increasing the speed of production and this brings me to the main characteristic of modern watchmaking; the employment of machine-tools and steam-power.

Let me say a few words as to the meaning of the term "machine-made watch," as I believe it is understood, even by all watchmakers. In a sense, every watch would answer to the definition, as tools and machines of various kinds are employed in its construction. But the term is generally of a more elaborate character, and driven by power. They are, of somewhat heavy construction, and a distinguishing feature is that, while they are made to facilitate their management, of repeating indefinitely a given operation with the utmost attainable accuracy, and under close supervision, is regarded as of primary importance. But this feature, the uniformity, is very easily made too prominent. It is possible to produce the plates, bars, cocks, and even the wheels and pinions, so that for all practical purposes, interchangeable when we come to the pivots, jewel-holes, various parts of the escapement, they are in the same sense, and it seems too much to

expect that machinery will ever make them so. I do not deny that it might be possible to replace any parts of one watch by the corresponding parts of another similar watch, but the chance of its keeping equally good time without further adjustment is small. Two pivots turned of the same thickness may require different degrees of polishing, and, therefore, their final diameters will differ. The accurate performance of an escapement depends on such a variety of conditions, that, although it may doubtless act when placed in a watch to which it does not belong, it cannot be expected to secure an equal rate without special adjustment.

I am aware that there is a considerable amount of opposition on the part of many watchmakers accustomed to the older system to the employment of machine-tools, but I venture to think that part of this is owing to a want of knowledge as to what may be legitimately expected of them, and part is probably due to the extravagant language too often employed in reference to this question. If our young watchmakers were brought up to be less exclusively watchmakers; if before making, say, an escapement, they could be induced to devote some of their time to a study of the tools they do use and might use, as well as to the actual making of such tools, there would, I feel convinced, be a natural tendency towards the principle of machine-tools. An ordinary pair of clockmaker's turns would, in the hands of an intelligent workman, lend itself to the construction of many devices for facilitating his daily work, and would often enable him to leave much of the work that now requires his personal supervision to a boy. Naturally, very little is known by watchmakers of the tools used in factories, but the kindness of many manufacturers, in London, Coventry, Prescott, and Birmingham, has enabled me to examine the machinery now in use, and I can most emphatically say that much of it will compare favourably with the watch itself in regard to accuracy of adjustment and beauty of finish. Tool-making is obviously of the first importance in a modern watch factory; and in Messrs. Rotherham's works at Coventry, I was much struck with a series of shops devoted specially to this branch, which appear to be provided with every available appliance for securing the most perfect workmanship in the machines they employ for watchmaking.

The history of the application of machinery to the watch manufacture has yet to be written. It appears that credit for its first suggestion cannot fairly be claimed by any one single inventor. Early in the present century, a number of manufacturers introduced it for special operations; and in 1839, Leschot established a machine-work movement factory in Geneva, which now belongs to the firm of Vacheron and Constantin. But P. F. Ingold, also a Swiss, appears to have first elaborated a series of both case and movement machines, their main feature being the production of any number of identical parts of a watch.

If we may credit the description given by Jurgensen of a machine designed by Ingold for making plates, they must have been extraordinarily complex. It was capable, he says, of producing a finished plate, polished, all the holes tapped for screws, steady-pin holes, including those for the escapement, with all the holes for the jewel

settings ready, sinks cut in the plate and polished both at the sides and bottom. His collection also included machines for making barrels, various parts of the escapement, together with balances, wheels, screws, and he had complete working drawings for watch-case machinery.

Ingold endeavoured unsuccessfully to establish a watch factory both here and on the Continent, and seems to have gone to the United States, about 1845, with the same object in view, but returned to Europe without having accomplished it.

In the report of the United States Commission on the Philadelphia Exhibition of 1876, group *xv.*, p. 90, it is stated that "In 1848, Mr. Dennison suggested to Mr. Howard the project of attempting the manufacture of watches by machinery, and two years afterwards, in company with Samuel Curtis, also of Boston, they established at Roxbury, Massachusetts, a factory of this kind. . . . The reporter mentions these facts as evidence that his countrymen "first conceived the project to manufacture watches by machinery" (p. 89). But the machinery can only have been applied to a few branches of the art, for it is inconceivable that two years after the project was "suggested," they could otherwise have "commenced the manufacture of watches." Anyone who has seen the extraordinary variety of machines that go to produce a "machine-made watch," must admit that, even in the present day of rapid production, and with all the designs ready to hand, two years would be a very brief interval in which to establish such a factory. And at the above date, 1848, several factories were already employing machines in Switzerland, more especially at Geneva. The credit, therefore, of having first applied machine-tools to the manufacture of watches must be given to the Swiss.

In saying thus much in regard to the earlier applications of machinery, I would, of course, not be understood to deny that very much has been done in America to bring the system to a high degree of perfection. It was there that a sufficient amount of capital was first embarked in the undertaking to render a trial to the fullest extent possible. The well-known inventiveness of the American people has largely extended the use of machines, and they have done much to prove their applicability to watchmaking.

It is not, however, my present purpose to enter even briefly on the history of this question. I wish rather to show how far tools are used at the present day in the production of both English and foreign watches. A mere verbal explanation, besides being dry and uninteresting, would fail to convince, but I am fortunate in possessing a number of specimens of machine work for exhibition here this evening. And I would take this opportunity of expressing my sincere thanks to various firms who have so readily responded to my request by sending samples of their work, which in many cases must have been got together with no little trouble. The firms to which I am thus indebted are given alphabetically in the following list, together with the nature of the objects lent:—

Mr. Ehrhardt, Birmingham—Frames, with pivot-holes drilled.

The English Watch Co., Birmingham—Keyless watches, and their several parts in all stages of manufacture mounted on cards.

Messrs. Guye, London—Keyless watch machine-made escapements, steel work, pivots, &c.

Mr. Hewitt, Prescott, Lancashire—Machine-made full,  $\frac{1}{2}$ -plate and  $\frac{3}{4}$ -plate, keyless, with steel work.

Messrs. Japy Frère, Beaucourt—Rough movement (*ébauche*), with train.

Mr. Mercer, Clerkenwell—Stages of manufacture by hand, of marine chronometer detent.

Messrs. Patek, Philippe & Cie., Geneva—Keyless movements, separate keyless mechanism and steel work.

Messrs. Rotheram, Coventry—Machine-made pinions, pivots, wheels, and wheel-blanks.

Mr. Taylor, Prescott—Chronometer wheels and pinions.

Mr. Tripplin, London—Details of finished Besançon watch.

The Waltham Watch Company, Mass.—Details of finished Waltham watch, with additional pieces showing pivoting, &c.

Mr. Wycherley, Prescott—Machine-made fusee movement; also detached pieces to stages of manufacture from rough metal.

I propose to exhibit a selection from the specimens in the lantern, but would at the same time mention that the series lent me by the English Watch Company is very complete. It comprises very great variety of pieces mounted on 13 cards, which may be regarded as typical of the operations in watchmaking to which machinery is applied at the present day. I am not aware that so complete a series has been previously exhibited in this country, and cannot but feel that the selection is worthy of very careful study. The machinery can be arranged to produce some of the elaborate pieces shown on these cards, it can make almost anything; and, whatever we may say to the contrary, interchangeability, there is no doubt that the process will require a far less amount of fitting than the old do on the hand system. It would be impossible for me to even enumerate the pieces that are exhibited, and I will only draw your attention to one very marked feature, the immense amount of labour that is saved by the use of the punch machine. There are very few pieces in either watch or case that do not in the first instance pass through this machine, and the amount of filing avoided must be immense.

It is difficult to form an exact estimate of the average number of machines employed in the manufacture of a watch. They will, in general measure, depend on the amount of production, since, of course, as this increases the tools will become more specialised. Mr. Gooding, of Messrs. Rotheram's, at Coventry, tells me that the number required for the movement, exclusive of that for the case, dial, hands, spring, and balance, may be taken at about 100, which is made up as follows:—

	Machines
Plate making .....	12
Wheel and pinion .....	35
Steel work .....	12
Escapement .....	23
Jewelling .....	11
Screws .....	6

Total .....

And he estimates the time occupied in making

hinery at 30 hours, about half that in the hand system.

is the third system of manufacture which is merely a combination of the two referred to. It is the most generally applicable, but evidently will include very many unanalysed establishments distinguished by the extent to which machine-tools are employed in the manufacture. The English system of the present day, as compared with that of 30 years ago, before movement making was superseded by means of machines, would not be included in this class. But what I rather include is the watch factory as we find it in this country, one that builds up timekeepers, but does not necessarily employ any special work as cases, dials, jewels, mainsprings, balances, &c., or even the parts of the movement. Several of the English firms to whom I have been for assistance this evening would thus be included. It cannot be doubted that such an establishment can turn out work of the highest quality at moderate cost, and it is an advantage, that it may be of any magnitude; the larger factory only includes the smaller in that it comprises all the branches of the trade, generally involving, which, if undertaken, might tend to reduce the cost of production. Thus, take the case of the dial-setting. In one factory that I have visited, the jewellers were able to do all the work. In another, therefore, that when less than half of the watches is made in the same time, it is not so constant employment for even the jewellers, and it might be more economical work done elsewhere. At the same time, it is presumed that the number of watches which this holds good will gradually approach a limit is reached, as the employment extends, for it will only involve the watches being idle for a definite period; or the other way, very general, of adapting a single system for several purposes would be applicable.

I have said enough with regard to the system of the present day, and will proceed to consider the other system, the hand system. At the outset one feature of the types of watch, with the exception of the Swiss movements, have gone to the making of movements that form the exception for completion on the hand system. It is evident that the going over to machine work far more readily, and one cannot but feel that an impetus for the opposition to the latter is in this fact. Enough has, however, been said on this subject, and I would now, admitting the applicability of the system to the manufacture of watches, this is not such a sound argument against the system as in ordinary watches.

The number of specimens illustrating the system of manufacture of watches, both on the hand and machine system, were here exhibited. They included many stages in the making of the movement as practised in the watch movements from Birmingham, Geneva, and London, as well as the cases and parts of watches lent by firms to whom reference has already been made. The images were obtained by direct

reflection of the beam from an electric lamp, thrown on the surface of the object. The light being incident at very small angle, an image was obtained, very slightly distorted and in natural colours.]

The examination of these specimens, even in the very inefficient mode I have been compelled to adopt, must suffice to convince an unprejudiced observer that, at any rate for watches of ordinary quality, machinery can be extensively employed with marked advantage. It secures a greater degree of uniformity in the work, a more rapid production, and may reasonably be expected to reduce the cost of the watch. How far its use is desirable in the highest branches of the art is a question for practical horologists to discuss. In the best English watches uniformity is not of the same importance, and minute economies need not be so carefully practised. Indeed, the present system is well adapted to their production, as is sufficiently proved by the fact that foreign makers have not succeeded in underselling us in this particular grade. Each instrument receives an amount of individual attention that would almost involve a direct contradiction of the main principle on which the application of machinery is advocated—a principle which is often expressed by that unfortunate word, interchangeability.

But the subject must be looked at from a very different point of view when we come to consider the cheaper class of watch; the branch of the trade in which so keen a competition is going on at the present day. Admitting that such a trade is worth preserving, and the statistics already given prove indisputably that it is, the question as to how it may best be fostered becomes a very urgent one, and I would make a few observations bearing upon it. At the outset, however, let me earnestly disclaim any desire to dictate to the trade; watchmakers know the details of their own business best, but what I do wish is to bring the matter more prominently forward, and to urge a more thorough discussion than has yet taken place, as to the reforms that can, with advantage, be introduced into the art, and the points in which we can take advice from our neighbours.

The general depression of trade cannot be held to be solely or even chiefly responsible for the present state of things. Within the last 30 years two new watch-producing countries have practically come into existence. France, although of course the trade has long been established there, has within that period increased its production ten-fold, and in America we have a new competitor. I have already pointed out that, judging from the official returns, we actually export from this country about the same number of foreign watches as of those of home production, whereas the imports for home consumption reach a total of about 250,000, or more than six times the total exports of home and foreign make.

At the risk of being considered a prophet of evil, I venture to refer to the state of the clock trade in this country as bearing on the subject we are considering. Fifty years ago we had a trade in clocks, and no one could have anticipated that, at the present day, it would be practically dead, the only exceptions being turret, regulator, and a few chime clocks, the value of the exports of which amounts to about £50,000. The Continent and America have taken possession of the entire

trade in ordinary timepieces; and in his official report on the 1878 Exhibition at Paris, M. Saunier mentions a fact in relation to it that is well worthy of note. While the production of the higher quality of clocks shows a tendency to fall off, or, at most, to remain stationary, the number of cheap clocks is increasing at a very rapid rate. Whether the same is to be said of watches we have no sufficient means of ascertaining, although the gradual fall in the mean price of English clocks and watches during the years 1867 to 1870, the last for which we have the requisite data, seems to point to some such conclusion; at any rate, it is not safe to hazard a guess as to whether such a tendency would continue: the mere possibility of it, however, indicates the necessity for our doing our utmost to preserve the watch trade intact, and not, as some would advocate, to surrender the cheaper trade without a struggle. At the same time, it is well to observe that there seems good reason to hope for an improvement in the average quality of watches in the future, independently of any advance in the horological art. As the habit of wearing a watch becomes more universal, the desire to possess one of superior quality may be expected to spread in even greater proportion, and the well-known tendency of modern life to make more and more use of our time, necessarily involves greater care in its accurate admeasurement.

I do not pretend to be able to explain the causes which have led to the destruction, more or less complete, of many branches of the horologist's art in this country, but would earnestly commend to all interested in it, the suggestive and most important address, devoted mainly to the subject of foreign competition, which was delivered by the Chairman of the Council of this Society, at the opening of the present Session. We may be sure that Mr. Bramwell had not watchmaking specially in his mind when writing that address; and yet there are many passages in it that might have been intended to have reference to this art. He says:—

"We shall find, it may be, that many of our industries are carried on according to the old traditions, traditions of practices which were the best known in the days when they were first employed, but which, under the teaching of science in other countries, have been abandoned as obsolete while they are retained by ourselves. We may find, paradoxical as it appears, that the fact of our having been engaged in any particular manufacture for many years obstructs our readily adopting the most improved form of carrying on that manufacture."

And there is one other passage in this address which I cannot refrain from quoting. Speaking of the field of work open to the Society of Arts, the Chairman says:—

"Why should it not put itself in communication with the manufacturers in some industry which is suffering its hold on foreign markets and, it may be, even its hold upon the home market, to be interfered with by the foreigner, to ascertain from these manufacturers whether the competition against them is succeeding on the score of price, or on that of quality, or on the score of the higher knowledge possessed, or the better taste displayed abroad. If it be on account of price, let us find out whether the disparity arises principally from

the labour question, or whether it arises, as it in countries where labour is dearer than in us, the use of improved processes in those countries, processes which we have failed to employ. . . . We have sufficient confidence in the skill and ability of our workmen, and the amount of capital available in this country, that it needs only that the true causes of the success of our competitors should be discovered, to make us all bestir ourselves to restore the threatened industry to its former safe position."

Would not watchmakers have real cause to be grateful if this Society would make their subject of investigation as suggested in the graph I have just read?

In another part of the same address the subject of Technical Education are brought prominently forward, and I am sure that no one will be prepared to doubt that horology ranks high among those industrial arts that involve the application of science for ensuring any real advance. I refer to this subject in the next lecture, and here only mention that it is one of the 32 subjects which examinations are annually held by the Board of London Institute for the Advancement of Technical Education.

It is highly improbable that a liberal machine-tools should not tend to amelio- rate the trade, when there is hardly another trade that has not received invaluable help from the watchmaker. Can he tell for himself, either by his own experience or such samples as I have seen, what degree of assistance it has afforded to the Americans, a people that, prior to about 1840, had no experience of the subject; how much it should it help us, when we have been practising as watchmakers for centuries.

When Arkwright patented his "spinning mule" there was a very great outcry against it, saying that it was a great outcry against it, saying that the manual skill of the workmen; but no objection can legitimately be made in this case. I have already been careful to point out that watchmaking exists, it will be impossible to make without a considerable amount of skilled labour for the adjustments, and this would be the case in the commonest of watches. I am sure that there should be no doubt whatever as to this point, and the most striking example I can give to adduce consists in a comparison of the prices of two watches manufactured in America, where, as is generally admitted, its use has been pushed as far as possible. They are movements of the same size; the one is approximately adjusted for heat and cold, and costs about £12, and the other, more highly finished, is quoted at nearly £50, more than five times the price of the first, and yet, to an observer, such difference as there is would be comparatively little moment. One may assume then that at least half of the value of the higher class watch has been on account of skilled labour. Thus we have no need to complain that any system has proved to be superior to that adopted in this country so far as regards the best work, as it is now principally needed is that the skill of competent workmen should be maintained. Machine work need not, then, degrade the skill of our artisans, and the fear that it will necessarily cause the English watch to be less artistic than at present is equally unfounded.

at a particular machine does not prove work is, of itself, no evidence against being able to do so, and there are specimens on the table to show that arms can be secured by such means. In the cheapest watch, what is wanted is and good timekeeping, and, if need-labour might be relied on for modifying according to taste in the higher grades. Rapid growth of the production of foreign as compared with our own, if it means must be taken as evidence that the English manufacture is not adapted to the cheaper watch. If it were, it would be simply im-possible more than a quarter of a million of cheap watches should be annually required to meet the demands of the home market.

It is, then, to be a peculiarly convenient and a new departure, and if several of the eminent manufacturers could be induced to take the matter into their consideration, how best to systematise the trade, as an example from our competitors, and if we would lay to heart the lesson which I have been able to collect teach him, possible but that much good would result. Various learned societies, the engineering professions, keep themselves abreast with the progress made, both at home and abroad, by their journals and their periodical meetings. The horologists of this country, although they have a monthly journal and a newly-erected museum, I think, admit that, as a body, they have not hitherto taken sufficient practical notice of it.

It is far from denying that many horologists are keenly alive to the necessity of improving the system so that it shall be more in accordance with the requirements of the present time. Their efforts have hitherto failed, owing to the difference with which every suggestion is received. Their journal and their institute do unquestionably good work, as a means of communication, and in keeping those engaged in the trade, by affording them a means of inter-communication; but a far higher work remains to be done by them, namely, the placing of the English trade on a satisfactory footing. The marks, although provoked by a comparison of the state of the trade in the cheaper watches, cannot but be more or less applicable to the case of higher qualities. At the present time, no mechanical art can afford to stand where the best English watch has its position, even that position is being assailed from several quarters, and it is time to be held without some effort.

It is evident from the specimens of watches on the table, we already possess in several factories more or less com-mingled up with machines for the manu-facture of watches on the modern system. But even the several establishments to which at- tention has been made does not disprove the English system of watchmaking is the best, and the problem that now urgently presents itself is how best to benefit those engaged in the manufacture, and, at the same time, to promote the trade of the country. All the temporary depression of trade may

be laid aside in discussing such a question, for it is a well-known and acknowledged fact, that even in times of commercial prosperity, the trade, taken as a whole, is in an unsatisfactory condition. For years past the cheaper watches sold in this country have been mainly of Swiss and French make, and America is now coming in for a share of the market. And here it may be well to observe that the English makers seem to be unwise in thus neglecting the cheap trade. Preach as you will about the comparative advantages of an English watch, if foreign makers can afford to sell a watch that is a fairly good timekeeper, and often more graceful than that made here for about twice the amount, there can be no wonder if it is in very many cases preferred. The fashion of wearing watches is gradually spreading through lower and lower grades of society, and if the home makers cannot or will not supply this demand, they have no right to complain of other countries taking the matter in hand. And it is unreasonable to suppose that we can hope to permanently retain the higher branches and so consistently neglect the lower. The entire trade is so small in extent that neither portion can afford to dispense with the other; indeed, the lower is, perhaps, of more service to the higher than the higher is to the lower, for, as it becomes more and more general to carry a watch, the inducement to those able to afford one of high quality to become possessed of one is greater; and only those who have tried the experiment know what a real satisfaction there is in being provided with a thoroughly reliable timekeeper.

How then are the interests of this beautiful industry to be best promoted? I do not pretend to be able to answer this question, but there are a few points to which, with your permission, I should wish to draw attention, in the hope that the subject may be earnestly taken up by others. In the first place, it must be admitted that the English system is not calculated to encourage radical improvements. Each workman through whose hands the watch passes is, as a rule, acquainted with only a small proportion of its details, and thus, through being unable to take a general view of the question, is placed in an unfavourable position as an inventor. The watch-jobber, into whose hands the watch comes for repair, stands a better chance of detecting faults of construction, and suggesting a remedy.

The extraordinary amount of independence to which the system has given rise, causes much needless expense and waste of time in the production of a watch. A number of trifling faults are often allowed to accumulate in the watch, each workman apparently leaving a legacy for his successor to correct. Thus it happens that some are sure to be left uncorrected, except in the very best work, and they secure the watch a bad name, if not at once, at any rate after a short time. Of course, on any method of manufacture there would be a risk of some such sources of error, and I am not pretending that these objections are peculiar to the English system. But a discussion lately held at the Horological Institute, at the instance of Mr. Bickley,\* seems to show that our system, with careful management, is capable of vast improvement: it is inconceivable that at the present

day so much double work as is done on an English watch is unavoidable.

And one obvious mode of avoiding it, at all events in great part, is the employment of exact machinery to the utmost extent. The most earnest advocate of the hand system cannot but admit that it is responsible for by far the greater number of these irregularities. A man, after making several hundred similar objects, such as screws, may, doubtless, arrive at making them alike by the sole aid of his sight and touch; but this is not true where only a few dozen specimens are made at a time, and they of a more complex form.

But how to popularise the use of machinery is a very difficult question. The factory system would certainly not be welcomed in Clerkenwell. And it may well be doubted whether its introduction would be advisable; the English system has so long consisted in a certain degree of isolation of various branches that efforts should rather be directed towards the improvement of this system, and the setting of it on a more satisfactory footing. Let Prescott retain the movement-making, Coventry the case-making, in addition to its own individual trade of watch-making, Clerkenwell the finishing, escapement-making, &c., but if the trade is to continue a trade, these several branches must work more into each other's hands. It is absurd that one man should systematically be called upon to undo the work of his predecessor, when by proper organisation all such contradiction might easily be avoided. In a watch factory each man, of course, works to a template, and it is surprising that there should be any occasion to advocate its use at the present day, in any of the mechanical arts that involve the production of a number of identical pieces. It is difficult to see why a common standard should not be introduced in the watch trade, and its adoption would constitute a very important step in adapting the English system of manufacture to modern requirements.

We have already seen, from an examination of Prescott movements, how far machinery is employed in what has been termed the "hand system," practised in this country. It is hardly open to question that its use might be extended with very great advantage; and if an accurate system of gauges and standards existed, might not the movement maker carry on the work to a certain definite point, and then hand it over to the Clerkenwell workmen, who would take it up where Prescott left off, without having to do over again any portion of what has already been done well. But it need not necessarily follow that the use of machinery would be confined to the movement-maker.

A principal feature of this system, which stands in the way of any material change, is the great number of small establishments that have to be kept up in Clerkenwell. They not only occasion delay, increase the cost, impede the introduction of improvements, and cramp the abilities of individuals, but they are, in too many cases, utterly unfit for occupation, and cannot fail to have a most detrimental influence on the character of the workman as well as on both the quantity and the quality of his work.

A suggestion recently made by Mr. Glasgow at a meeting of the Horological Institute is worth careful consideration as bearing on this question.

Would it not be practicable to establish in Clerkenwell, one or more large shops, where work all the branches of the trade could rent and as they required? How many advantages be secured by some such arrangement? It would not only secure a healthy place of business specially adapted to their several requirements and away from their homes, but would bring them more in contact with each other and the trade generally. But I venture to think this scheme might enable them to secure another advantage in some respects, a yet more important advantage. It would immensely facilitate the introduction of modern improvements, both in the work and in the tools employed in its production. Steam power might also be let to the tenants there can be little doubt that the possession of such power would act as a powerful incentive to the use of the tools wherever desirable. Working to the same end as the gauges above referred to, the new might thus be taken in hand as received by Prescott, and pass through the several stages to make up the Clerkenwell branch of the system.

I could not pretend, even if this were an occasion, to follow out the above suggestion all its details. It is essentially a question of practical watchmakers, and if this or any other scheme, having similar objects in view, has your cordial support, much will have been done that we are, to again quote the words of Bramwell, "effectually bestirring ourselves to restore the threatened industry to its former position."

## MISCELLANEOUS.

### LONDON FISH SUPPLY.

The following statistics relating to the fish brought into London by the various railway companies, have been elicited by the inquiry into the Corporation of London, and now being made in the Upper Court, Guildhall.

Mr. W. Birt, general manager of the Great Eastern Railway Company, said his company carried 10,000 tons of fish to Billingsgate last year from the east and north-east coast. Prime fish, a risk, was carried at 32s. 6d. per ton, and off fish at 21s. 8d. per ton, from station to station. This included the market dues, but not the delivery if performed by the company, was charged for extra. It was at the option of the sender whether they sent at their own or the company's risk, as a fact about 96 per cent. was sent at the company's risk. The company's risk was 6s. 8d. per ton for prime fish and 3s. 4d. per ton for off fish. The difficulties at Billingsgate were very great. A return was made on this year, when it was found that upon an average a van was delayed four hours at the market. The experience of his company it appeared to be that two or three markets were needed in London to meet the demands of the fish business of the port rather than one central market, and so improve the trade with the necessity of such a change, that it was out of the large works to be constructed at Billingsgate they had set aside about two and a quarter acres to be used as a fish market for railway use. Such a market would save the 5s. now charged for cartage. His company not only proposed to improve the market, but to erect nine warehouses in it

le could be carried on. Should an improvement be in the fish market of London with greater facilities unloading, and should the supply of fish increase, had no doubt that his company would reduce their rate.

Mr. J. Noble, general manager of the Midland Railway, said his company carried 9,280 tons of fish to London in 1880. Haddocks and plaice from Hull and Mablethorpe were charged 35s. per ton; that did not include delivery. Some fish was sent by passenger train, the extra cost of that was from 6s. to 9s. per ton, according to the kind of fish. The delivery of tanks involved an extra charge of 10s. for cartage. Regarding questions, the witness said his company had a quantity of land at their disposal at St. Pancras, and he thought of allocating a portion of it as a fish market. He was in favour of a large central market with easy access.

Mr. H. Oakley, general manager of the Great Eastern Railway Company, said his company conveyed 26,543 tons of fish to Billingsgate last year. Rates varied from 30s. to 70s. for coarse fish from London. The average rate for prime fish was 46s. 8d. from Hull and Grimsby. The greatest difficulty was experienced near Billingsgate in getting vans up to the station. They allowed three hours and a-half for their delivery to the fish at the market, but, as a rule, it varied between six and seven hours, and sometimes more. In fact, it took as long for a van to go from the docks, deliver the fish, and return, as it did to carry the fish by train 200 miles through the country. The rates he had quoted did not include delivery, for which a charge of 5s. was made. A central market in the streets running through it, and easy of access, would be very desirable in the interest of both buyer and seller.

Mr. D. Stevenson, traffic superintendent of the London and North-Western Railway, said that about 100,000 tons of fish were conveyed by his company to Billingsgate last year. The rate from Scotland was 55s. per ton by passenger train and 55s. per ton by goods train. For goods by passenger trains an extra charge of from 4s. to 6s. was made. To make Billingsgate large enough, it would be necessary to throw into the market an uncovered land of the Custom House on the one side and on the other the land covered by Nicholson's street, up as far as London-bridge. He thought there should be two markets, one for water and the other for land-borne fish. The charge for the carriage of fish from Liverpool was charged 26s. per ton, while from Holyhead was 55s.; that was on account of the risk attached to the carrying of fish.

Mr. H. Lambert, chief goods manager of the Great Eastern Railway, said that his company conveyed 10,000 tons of fish to Billingsgate last year. The cost of carriage from the West of England was 60s. per ton, from New Milford 65s. 6d. All fish trains ran at a fast speed, and the company undertook to supply a goods train within three hours whenever the senders required a supply of 20 tons weight. Although quickly sent to London, it often took from four to eight hours to get it delivered at the market. He did not think the present market, however much improved, could be made a suitable market for all London.

Mr. Mortimer Harris, manager of the London, Chatham, and Dover Railway, said that his company conveyed 2,530 tons of fish to Billingsgate in 1880, for which they charged a rate of 22s. per ton for coarse fish, and 40s. for other sorts. He was favourable to the establishment of several markets in the metropolis near the railway termini.

Mr. J. Light, goods manager of the South-Eastern Railway Company, said that 3,071 tons of fish were sent by his company last year. The rates from Mablethorpe were, for prime fish, 40s. per ton; and 22s. for coarse fish.

Mr. Arthur Johnson, fish meter, was examined, and said that his duty was to inspect all the fish as it came on the vans, and also by boat, into the market. The quantity which was received could not be given accurately, as it varied each month. Sometimes 500 tons would arrive, other days 830 tons would be received. The average quantity sent to Thames-street, Billingsgate, and into the market, was 1,700 tons per month altogether. During the last six months, from the 1st of January to the 30th of June, the quantity condemned was forty tons per month, of which one-third was shell fish and the other wet fish, such as plaice and haddocks. If the market had been ten times the size it was, it would have made no difference, as a large quantity of the fish so condemned was seized in the railway vans. The delay in the vans could not be helped. The fish was condemned chiefly between six and seven in the morning, when it came into the street. The bulk of the fish was condemned on the Monday, which was on account of its being delayed on the Sunday. That would happen in any market. He was of opinion that the fish condemned on Monday was bad before it left the railway station. They threw the condemned fish into tanks filled with acid. While this condemned fish was being unloaded the space in the street was being taken up, and prevented the business going on until it was cleared away. He was authorised by the Fishmongers' Company to seize fish on his own responsibility. It was not always necessary to call in another inspector before condemnation. The quantity of fish coming by water varied very much.

This subject of fish supply is one in which the Society of Arts has always exhibited the greatest interest. As early as 1761 the Society advanced the sum of two thousand pounds to Mr. John Blake, for the purpose of carrying out his scheme for the supply of the markets of London and Westminster from distant sea ports and rivers by land carriage. During the last few years the subject has been considered by the Food Committee.

## PANAMA CANAL.

A correspondent of the *Journal des Débats*, writing from Panama, gives an account of the progress made thus far with M. de Lesseps' great undertaking. The first practical work of any importance yet completed, is the construction of a grand pathway from Colon to Panama, which has been cleared of trees and other obstructions to a width varying from 30 to 60 feet. Now that this clearance has been effected, it is possible for the first time to get a clear idea of the work which is before the company. Hitherto, it has been only by rather vague guesses that the lie of the surface could be conjectured, inasmuch as the thick foliage of the trees, spreading over the valleys and ravines, often made it difficult even to see that these existed. If it was assumed, as the *Débats* thinks, that in these cases the ground was as flat as the tops of the trees, then the discovery of deep depressions so arched over will be a great gain in estimating the extent of the excavation works. There is, however, another point in which the most recent explorations are regarded as unexpectedly favourable. It was assumed when the plans were made that all along the route of the projected canal a stratum of hard rock would be found underlying the soil at a depth of about twelve feet. But at Emperador, where the principal borings have been made, it is stated that on March 31 the instrument had reached a depth of 37 feet without finding any rock, and even at that point the rock which appeared was only a layer about six feet thick, succeeded underneath by a mixture of clay and soft stone, which went down to a depth of 64 feet, where the bore was still working lately without encountering any rock. It is now said that the excavation works will be begun about October next, after the rainy season, and in the meantime the preparatory

operations are being actively carried on by companies of workmen, recruited from amongst the inhabitants and from Carthagens, whence they have been driven by an invasion of locusts.

## NOTES ON BOOKS.

**Suggestions in Design**, being a Comprehensive Series of Original Sketches in Various Styles of Ornament, arranged for application in the Decorative and Constructive Arts. By John Leighton, F.S.A.; with descriptive and historic letter-press by James K. Colling. London: Blackie and Son. 4to.

As long ago as 1852, Mr. Leighton published a work with the same title, under the *nom de plume* of Luke Limmer, which contained the nucleus of the present book in the shape of 47 plates. The author has revised and re-drawn these, and added more than an equal number of fresh illustrations. The object is to present a large series of designs conceived in the spirit of a considerable variety of styles of art, which may be useful to artists. These plates "are intended as aids to design rather than for servile imitation or direct appropriation, serving to represent the type of many designs, and not the exact portraits of any. The object of the author, therefore, being to present suggestions, leaving the designer or art workman to modify or adapt them to his own purposes, it is hoped that the book will be found eminently suited to the wants of all engaged in decorative and ornamental work." The subjects are arranged in the following order:—First, those of general periods and nationalities—Savage tribes, Egyptian, Assyrian, Greek, Etruscan, Pompeian, Roman, Chinese, Japanese, Indian, Persian, Moorish, Byzantine, and Gothic. The Renaissance is seen in some of its various developments, then more special conceptions are shown in floral decorations, figures, chimeras, &c. Designs for metal work, inlaying, blazonry, &c., are also given. In the descriptive letterpress, the various points, as shown in the plates, are taken up *seriatim*, and the general principles of design have a special chapter devoted to their discussion.

**A Practical Treatise on Coach-Building—Historical and Descriptive.** By James W. Burgess. London: Crosby Lockwood and Co. 1881.

The author affirms that it is over fifty years since an exhaustive book on the trade of coach-building has been published, and he has, therefore, attempted in this hand-book to point out the general principles upon which carriages should be constructed. The first chapter is devoted to a general history of the subject, from the Egyptian war chariot to the carriages of to-day. The various parts of a carriage, the painting, the lining, &c., are treated of in subsequent chapters. In the general remarks on the trade, a hopeful view is taken of the increased skill and ingenuity of the coach workman, and the author alludes to the beneficial influence of the Exhibitions of the Coachmakers' Company.

**The Diamonds, Coal, and Gold of India, their mode of Occurrence and Distribution.** By V. Ball, M.A. London: Tribner and Co. 1881.

Mr. Ball designs his book as a hand-book to the detailed accounts of the more useful mineral deposits of India, published by the Geological Survey of India and other authorities, the results of which thorough explorations have not hitherto, he believes, been introduced into text-books. With regard to diamonds, he believes the Koh-i-nur to be identical with the Great Mogul diamond described by Tavernier,

which came from Kollur. The author is of opinion there is not the least ground for supposing localities where mining is possible have been and he thinks that if Europeans would diamond mining in India, they would find it. Of the other two subjects treated of in this author gives an account of the various coasts tributary over the whole of India, and of producing tracts, which consist of Wynad in Madras; Dharwar, Belgaum, and Kaland, bay; Central Provinces, Orissa, South-West North-West Provinces, including Himal Punjab; and Ultra-peninsular areas, such as Burmah, Afghanistan, and Thibet.

**Sketches in Water Colors.** By Various (Vere Foster's) Drawing Books, Extended London: Blackie and Son. Three parts,

These sketches consist of chromo-lithographic drawings, by F. M. Richardson, R.P. Leitch, J. A. F. L. Rowbotham, E. Duncan, and J. Neel. Full directions are given as to the way in which they may best be copied by the learner.

**Easy Studies in Water Color Painting.** Leitch and J. Callow. London: Blackie

The nine chromo-lithographs here given are for the use of those students who have already acquired proficiency in pencil drawing, and wish to acquire knowledge of the art of landscape painting in colours.

## GENERAL NOTES.

**Institution of Mechanical Engineers.**—A meeting of the institution will be held this evening at the castle-on-Tyne, from Tuesday, 2nd, to Friday, 5th. There will be excursions on each day, and a large number of Works will be open for the inspection of the Secretaries' office will be open on Monday, 1st, at the Memorial Hall, Newcastle-upon-Tyne.

**Technological Hand-books.**—Messrs. Geo. Sons are preparing for publication a series of 12 Hand-books for the use of candidates in the 12 Examinations, which, instituted by the Society in 1873, were, in 1879, transferred to the City Institute. The rapid increase in the number of candidates since the examination scheme was remodelled, and examinations have been supported by the friendly associated Guilds, is considered to justify the belief that these hand-books will be successful, since there are many artisans and others who are seeking to become familiar with the theory of their speciality. It is intended by the publishers eventually to issue a series of all the industries specified in the program of the City Institute; but at first those branches of the trade which have been selected for treatment in which it is believed that text-books are most required. In accordance with this plan six books are now announced for publication: Bleaching, Dyeing, and Printing, by Willis F.R.S., V.P.C.S.; "Iron and Steel Manufacture," by K. Huntington, F.C.S., F.I.C., Professor of Metallurgy at King's College, London; "Telegraphs and Cables," by W. H. Preece, F.R.S., Memb. Inst. C.E., &c.; "The General Post-office"; "Cotton Manufacture," Part I, Spinning; Part II, Weaving; by R. Marsden, J. Textile Manufacturer. "Glass Manufacture," by Sheet, and Plate Glass, by Henry Chance, M. Brose, Birmingham; "Flint Glass," by H. P. Whitefriars Glass Works; "Optical and Light," by John Hopkinson, M.A., LL.D., F.R.S. These are issued under the general editorship of H. T. Sturt, the Secretary to the Society of Arts.

## OF THE SOCIETY OF ARTS.

No. 1,498. Vol. XXIX.

IDAY, AUGUST 5, 1881.

one for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.

## NOTICES.

## FURNITURE EXHIBITION.

Exhibition of Works of Art Applied to  
in connection with the Exhibition of  
at the Royal Albert Hall, is now open  
on-transferable season ticket will be  
member of the Society on application  
tary.

## EDINGS OF THE SOCIETY.

## PATENT-LAW AMENDMENT.

Committee appointed for the purpose by  
have prepared a draft Bill, which has  
ted to the Council and approved by

in accordance with the instructions of the  
the Bill is now published for the con-  
of the members and of the public, as  
first draft of a Bill which, in the opinion  
of the Council, embodies the essential provisions  
of the present Patent-law.

The Council will summon a public meeting in  
order for the discussion of the Bill, after  
which resolutions will be taken to obtain its intro-  
duction into Parliament, in the Session of 1882.

Enclosed is a list of the Committee by  
which the Bill has been prepared:—Sir Frederick  
P.R.S. (Chairman); F. A. Abel, C.B.,  
and Carpmael; Sir Henry Cole, K.C.B.;  
and Glas Galton, C.B., F.R.S.; W. H.  
P.R.S.; C. W. Siemens, LL.D., F.R.S.;  
and Truman Wood (Secretary).

The Secretary will be glad to receive from  
the Society and others any observa-  
tions or amendments on the Bill which they may  
send for the consideration of the Com-

The Bill has been printed in the usual form, and  
may be had on application at the Society's  
Office.

H. TRUMAN WOOD, Secretary.

The following is the full text of the Bill:—

## ARRANGEMENT OF CLAUSES.

## PREAMBLE.

	References to similar Clauses in Patent Law Amendment Act 1852.	References to similar Clauses in Government Patent Bill 1876.
<b>PART I.</b>		
<i>Preliminary.</i>		
1. Short title, extent, and commence- ment of Act .....	56, 57	1, 2
2. Repeal of scheduled enactments and of rules .....	..	3
3. Interpretation of terms .....	55	4
<i>(i.) Exception from Statute of Monopolies.</i>		
4. Patents excepted from Statute of Monopolies .....	55	..
<i>(ii.)—Subject Matter of Patents.</i>		
5. Subject matter for which a patent may be granted .....	55	..
6. To whom a patent may be granted..	..	24

SCHEDULE:				

**FT OF A BILL TO CONSOLIDATE WITH AMENDMENTS THE LAW CONCERNING LETTERS PATENT OR INVENTIONS, AND FOR OTHER PURPOSES.**

Whereas it is highly important, for the good of the Arts Manufactures and Commerce of this country, that new and meritorious inventions should receive all possible assistance and encouragement; and whereas the existing law does not sufficiently secure property in an invention to its true inventor, or offer him such encouragement as may induce him to develop his invention for the public benefit, and is in other respects defective and ill-calculated to promote the progress and growth of such inventions as aforesaid; and whereas it is therefore expedient that the law concerning Letters Patent for Inventions be amended and consolidated; and whereas it is enacted by the Queen's most Excellent Majesty by and with the advice and consent of the Lords Spiritual and Temporal and Commons heretofore present Parliament assembled and by the authority of the same as follows:

**PART I.**

*Preliminary.*

—(1.) This Act may be cited as the **Patent<sup>s</sup> Inventions Act 188**.

(2.) This Act extends to the Channel Islands and the Isle of Man.

(3.) This Act comes into operation (except where otherwise expressed) on the *first day of January 188*, which time is herein referred to as the commencement of this Act.

The Acts described in the First Schedule to this Act are hereby repealed as from the commencement of this Act to the extent in that Schedule mentioned.

All rules and regulations made under any of the Acts repealed by this Act are also hereby repealed as from the commencement of this Act.

In this Act—

“The Statute of Monopolies” means the Act of the twenty-first year of the reign of King James the First, chapter three, intituled An Act concerning Monopolies and Dispensations with Penal Laws and the Forfeiture thereof:

“Invention” means anything which may be the subject of the grant of a patent under this Act, and includes an alleged invention:

An invention is deemed new for the purposes of this Act if it has not been published or publicly used in the United Kingdom the Channel Islands or the Isle of Man, within the *thirty years* immediately preceding the date of the application for the patent for it:

“Patent” means letters patent for an invention:

“Applicant” means applicant for a patent:

“Patentee” means the grantee of a patent, and includes his executors administrators and assigns:

“Examiner” means an Examiner of Patents under this Act:

“Commissioner” means a Commissioner of Patents under this Act:

“Expert” means a person specially qualified by his knowledge of manufactures or science or arts to assist the Commissioners

of Patents in the case in which his assistance is sought:

“Abroad” means out of the United Kingdom the Channel Islands and the Isle of Man:

“The Treasury” means the Commissioners of her Majesty's Treasury or two of them:

“The High Court of Justice” means her Majesty's High Court of Justice in England or Ireland, as the case may require:

“Prescribed” means prescribed by general rules made by the Commissioners of Patents under this Act:

For the purposes of this Act a year in relation to a patent is reckoned as beginning on the day, or the anniversary of the day, of its date, and ending at the end of the day next before the anniversary of the day of its date.

(i.)—*Exception from Statute of Monopolies.*

4. All patents duly granted under this Act are hereby excepted from the operation of the Statute of Monopolies, and shall not be invalidated or affected by anything therein contained.

(ii.)—*Subject Matter of Patents.*

5. A patent may be granted under this Act for—

(a.) Any manufacture or any product not being a natural product;

(b.) Any machine or any means of producing any manufacture product or result;

(c.) Any process or method of producing any manufacture product or result;

(d.) Any part of a machine means process or method of producing any manufacture product or result.

6.—(1.) A patent may be granted to any person, whether a British or foreign subject, declaring himself to be the inventor of an invention within the meaning of this Act, or to his executors administrators or assigns or to his or their attorney or agent, subject to the provision made by this Act for inventions patented abroad.

(2.) Where two or more persons declare themselves to be the joint inventors of an invention within the meaning of this Act, a patent may be granted to them in their joint names, subject to the like provisions as in the case of a single patentee

7.—(1.) Where a grant of privilege has been made by letters patent or otherwise for the monopoly or exclusive use or exercise abroad of an invention, a patent for that invention can only be granted to the foreign or colonial grantee, or his legal personal representative (by himself his attorney or agent); and can only be granted to him on his written application within *twelve months* from the date of the foreign or colonial grant, or of the earliest of them if more than one, or where the same is or are existing at the commencement of this Act, then within *twelve months* after the commencement.

(2.) The patent if granted, shall not be affected by the publication of the invention in the United Kingdom the Channel Islands or the Isle of Man by means only of the circulation or republication therein within those *twelve months* of copies of any foreign or colonial grant in respect of the invention or of any specification or other document connected with that grant.

(3.) The patent if granted shall not be affected

as to duration or otherwise by the expiration or determination in any other manner of the foreign or colonial grant.

(iii).—*Commissioners of Patents and Examiners.*

8.—(1.) There shall be a Board of Commissioners of Patents for Inventions, in this Act referred to as the Commissioners :

(2.) At any time after the passing of this Act her Majesty may, by warrant under the Sign Manual, appoint three persons to be Commissioners, of whom one shall be experienced in engineering, one shall be experienced in chemistry, and one shall be experienced in the law :

(3.) On the occurrence of any vacancy her Majesty may from time to time in like manner appoint a person of qualifications similar to those of the vacating Commissioner to fill the vacancy :

(4.) The Commissioners shall have an official seal, and impressions thereof shall be judicially noticed and admitted in evidence.

9.—(1.) The Commissioners may from time to time after the passing of this Act, subject to the approval of the Treasury, appoint such persons qualified by knowledge of manufactures or science or arts, as they see fit, to be Examiners of Patents.

(2.) The instrument of appointment shall in each case state the opinion of the Commissioners that the person appointed is so qualified.

(iv).—*Application for Patent.*

10.—(1.) An applicant for a patent must lodge at the Patent-office an application and declaration in the prescribed form, accompanied by a specification describing the nature of the invention (in this Act termed the Provisional Specification).

(2.) Notice of the application, but not of the contents of the provisional specification, shall be published by the Commissioners.

(3.) On the grant or refusal of a patent, or on failure to prefer a request for sealing within the time allowed, the provisional specification shall be destroyed in the Patent-office; and until it is so destroyed its contents shall be kept secret.

11. The publication or public use of the invention after the application and within a period of *nine months* from the date of the application shall not prejudice the grant of a patent for the invention (which protection from the consequences of publication or public use is in this Act referred to as Provisional Protection).

12.—(1.) The application and its accompanying documents shall be referred by the Commissioners to an Examiner, who shall report to them his opinion—

(a.) Whether the invention is subject-matter for a patent ;

(b.) Whether the title of the invention sufficiently indicates its nature, and whether the provisional specification is in accordance with the title.

(2.) A copy of the report shall be furnished to the applicant, and he may within the prescribed time appeal to the Commissioners against it.

(3.) If the Examiner reports against the title and the provisional specification or either of them, and his report is not appealed against, or is affirmed on appeal, the application shall not be further proceeded with, unless the applicant

within the prescribed time amends the title and the provisional specification as the case may be to the satisfaction of the Commissioners.

(4.) If the Examiner reports that the invention is not subject-matter for a patent, the applicant may, notwithstanding that his report is on appeal, be proceeded with ; but in the every copy of the patent if granted as of the office copy of the specification shall bear a short statement of the report of the Examiner.

13.—(1.) At any time during, and not less than *three months* before the expiration of, the period of provisional protection, the applicant may at the Patent-office a further specification particularly describing and ascertaining the nature of the invention and in what manner it is performed (in this Act termed the Complete Specification or the Specification) together with a request for the sealing of the patent.

(2.) If he fails to do so, the provisional protection shall cease and the application shall be proceeded with, save by special leave of the Commissioners, on proof to their satisfaction of a reasonable excuse for the failure.

14.—(1.) The applicant may, if he thinks fit, instead of lodging a provisional specification, lodge a complete specification and request for the sealing of the patent, together with his application and declaration in the prescribed form.

(2.) In that event the provisions of the Act relating to the provisional specification shall not apply.

15.—(1.) On the lodging of the complete specification the Commissioners shall again refer the application to an Examiner.

(2.) The Examiner shall report to the Commissioners his opinion—

(a.) Whether the complete specification is in accordance with the title and with the provisional specification (if any) ; and whether the applicant shall be allowed time before the Examiner reports, to amend his complete specification by omitting from any matter contained in the provisional specification.

(b.) Whether the claim of the applicant is defined with sufficient clearness.

(3.) A copy of the report shall be furnished to the applicant, and he may within the prescribed time appeal to the Commissioners against it.

(4.) If the report of the Examiner on the complete specification submitted to him is adverse to the applicant and is not appealed against or is affirmed on appeal, the application may nevertheless be proceeded with ; but in that event every copy of the patent if granted and every office copy of the specification shall bear on it a short statement of the report of the Examiner.

16. The Commissioners shall publish the complete specification as soon as may be after the application is settled, and thereupon for the residue of the period of provisional protection, or (where the provisional specification has been lodged) for the residue of the period of *nine months* after lodging the complete specification, the applicant shall have the like private rights as might have been conferred by the Act for the invention sealed as of the date of the application.

17.—(1.) The Commissioners shall pay

appointed by them for considering the patent.

Any person may, within the prescribed time, object to the Commissioners of his intention to grant, on the ground of the application obtained the invention from him, but on any ground.

The Commissioners shall hear such person, and any person entitled to be heard, as well as the applicant, before the expiration of the period of protection, or (where no provisional application has been lodged) of the nine months following the complete specification.

The decision of the Commissioners is in favour of the grant, the Commissioners shall cause the patent to be sealed with their seal a patent in the second schedule to this Act, or in any form as may be prescribed.

Every patent shall be dated the day of the issue for it [save that, where the Commissioners direct, a patent may be dated the day of the issue or any day between the day of the issue and the day of sealing.]

A patent shall be sealed as of the day of the issue.

It shall not be competent for the Commissioners to take any proceeding in the respect of the patent committed before them on the ground of the complete specification.

The term limited in every patent for the invention shall be *seventeen* years from its date.

A patent when sealed shall have effect throughout the United Kingdom the Channel Islands and the Isle of Man.

Every patent shall notwithstanding anything in or in this Act, cease at the end of the *fourth* or the *eighth* year of its term, unless the patentee takes out at the Patent-office an application for renewal which shall be granted on any writing.

Nevertheless, in any case, by accident or inadvertence, the patentee fails to take out a certificate of renewal, he may prefer an application to the Commissioners for an enlargement of the term or taking it out.

Upon the Commissioners may if they think fit enlarge the time accordingly, but not in any case to extend beyond *six months* from the *fourth* or the *eighth* year aforesaid (as may be).

A proceeding shall be taken in respect of the patent committed within the enlarged term or special leave of the Commissioners.

#### *—Amendment of Specification.*

An applicant for a patent or patentee may, by written request to the Commissioners, amend his complete specification by addition or disclaimer, stating reasons therefor.

A request shall be published by the Commissioners and the applicant or patentee shall be heard thereon by an Examiner, or the Commissioners, in the prescribed manner.

A request shall be granted by the Commissioners if their being satisfied that the amendment will make the specification comprise an

invention substantially larger than or substantially different from the invention originally claimed.

(4.) Any person giving notice within the prescribed time to the Commissioners of objection to the amendment on the ground that it would make the specification comprise an invention substantially different from the invention originally claimed, shall be heard in support of his objection.

(5.) An amendment shall not be admissible in evidence in a proceeding for an infringement alleged to have taken place before an amendment, nor in any proceeding pending at the time of request for leave to amend, except a proceeding for revocation of the patent.

(6.) Leave to amend shall be conclusive as to the right of the party to amend, except in case of fraud.

#### *(vi.)—Prolongation of Patent.*

24.—(1.) A patentee may within the prescribed time before the expiration of his patent apply to the Commissioners for a prolongation of its term:

(2.) The Commissioners shall publish notice of the application, and of the time fixed for hearing it:

(3.) Any person interested (including a representative of the Crown if interested but not otherwise) may on giving the prescribed notice to the patentee appear at the hearing and oppose the application:

(4.) The decision of the Commissioners on the right, (if challenged) of any person to appear, is final.

25.—(1.) The Commissioners after hearing the case may refuse the application, or may order the prolongation of the term of the patent for any period not exceeding *eleven* years, as they may see fit:

(2.) In determining the case the Commissioners shall have regard to all the circumstances, and in particular to the merit and utility of the invention, to the patentee's expenditure of labour and money, and to the amount of his profits as patentee, considered in relation to the benefit derived by the public:

(3.) It shall not be competent for the Commissioners to impose any conditions in respect of an order for prolongation:

(4.) The order shall be endorsed on or annexed to the patent, and the term of the patent shall be prolonged accordingly.

#### *(vii.)—Stamp Duties.*

26.—(1.) There shall be paid to and for the use of the Crown on the several instruments described in the *third* schedule to this Act the Duties in that schedule mentioned and no others:

(2.) Those duties shall be under the management of the Commissioners of Inland Revenue, and shall be deemed stamp duties within the Stamp Duties Management Act 1870 and other Acts relating to stamp duties, particularly those relating to forgery fraudulent dies and other offences in connexion with stamp duties:

(3.) Any of the stamps may be adhesive if the Treasury think fit.

#### *(viii.)—Crown.*

27.—(1.) A patent shall have to all intents the

like effect as against her Majesty the Queen her heirs and successors as it has as against a subject :

(2.) But for purposes of the naval or military service of the Crown one of her Majesty's principal Secretaries of State or the Lords Commissioners of the Admiralty may, by their officers agents contractors or others, at any time after the application for the patent, use the invention on terms to be before or after the use thereof agreed on, with the approval of the Treasury, between some duly authorised representative of the Crown and the patentee, or in default of such agreement to be settled by the Commissioners after hearing the representative of the Crown and the patentee, if desirous respectively of being heard :

(3.) All expenses of the hearing shall be paid as part of the expenses of the Commissioners in the execution of this Act.

(ix.)—*Assignment and Licenses.*

28. A patentee may assign his patent for England, or for Scotland, or for Ireland, as effectually as if the patent were originally granted to extend to England only or to Scotland only or to Ireland only.

29.—(1.) On complaint and proof to the satisfaction of the Commissioners—

That by reason of default of the patentee to grant licenses or otherwise, the reasonable requirements of the public with respect to his invention cannot be supplied ; or

That any person is in possession of an improvement on the invention which he is prevented from working or using, by reason of the patentee refusing to grant him a license on reasonable terms ;

Then and in either of such cases the Commissioners may, on the application of any person interested, order the patentee to grant licenses on such terms as to amount of royalties, security for payment, leave to the patentee to use any improvement, and otherwise, as to them, having regard to the nature of the invention and to all the circumstances of the case, may appear just.

(2.) On complaint and proof to the satisfaction of the Commissioners that a patentee has failed to comply with an order made under this section, the Commissioners may, if they think fit, after hearing the patentee if desirous of being heard, either require him to give security for his compliance, or may revoke his patent without prejudice to the rights of existing licensees.

[(3.) But the patentee may, if he thinks fit, in lieu of granting licenses pursuant to an order of the Commissioners, require any applicant for a license to purchase all his rights under the patent at a price to be fixed in default of agreement by the Commissioners.]

(x.)—*Registers of Patents and Proprietors.*

30. There shall be kept at the Patent-office a book or books called the Register of Patents, wherein shall be recorded in chronological order all patents granted under this Act, the lodging of specifications amendments of specifications certificates of renewal prolongations of patents the expiration or revocation of patents, with the dates thereof respectively, and such other matters concerning patents as the Commissioners direct.

31.—(1.) There shall be kept at the Patent-office a book or books called the Register of Patents, wherein shall be recorded any assignment of a patent or of any share or interest therein under a patent and the expiration of the term of the patent.

(2.) Until an entry of an assignment or of any share or interest therein or an assignment under a patent, is made in the Register of Proprietors, the original patentee shall be deemed to be the sole proprietor of the patent, and shall not be liable to have granted any license thereunder.

(3.) An entry in the Register of Proprietors shall be proof of the assignment or license or of the share, as therein expressed, until the contrary is proved.

32. The Register of Patents and the Register of Proprietors, or copies thereof respectively open to public inspection, on payment of not exceeding one shilling, and subject to any regulations made by the Commissioners.

33.—(1.) The High Court of Justice in or a judge thereof, may at the instance of any person deeming himself aggrieved by a patent made under colour of this Act in the Register of Patents or the Register of Proprietors, order for expunging or varying that entry with respect to the costs of the proceedings in the court or judge thinks fit :

(2.) The entry shall be expunged or varied accordingly.

(xi.)—*Revocation of Patents.*

34. The proceeding by *scire facias* to revoke a patent is hereby abolished.

35.—(1.) A patent may be revoked by the Commissioners on the petition of any person on any of the following grounds :—

- (a.) That the invention is not new within the meaning of this Act ;
- (b.) That the patentee is not the true inventor ;
- (c.) That the specification is in substance misleading :

(2.) Where a patent has been found to be invalid by the Commissioners in a proceeding for revocation, it shall, unless within the prescribed period the ground of invalidity is removed by the applicant, be revoked by the Commissioners.

36. Where a patent for an invention is found to be invalid by the Commissioners on the petition of the true inventor, the Commissioners may, if they see fit give to the true inventor his costs of the hearing as between solicitor and client.

(xii.)—*Foreign Vessels.*

37.—(1.) A patent shall not prevent the use of an invention for the purposes of the navigation of a foreign vessel within the jurisdiction of Her Majesty's Courts in the United Kingdom, or the use of an invention in a foreign vessel that jurisdiction, provided it is not used for or in connexion with the manufacture or preparation of anything intended to be exported from the United Kingdom :

(2.) But this section does not extend to any foreign State in whose territories subjects do not enjoy equal benefits in the subject-matter of this section.

*Industrial and International Exhibitions.*

The publication or use of an invention at an industrial exhibition or at any international exhibition for the purposes of such exhibition and the place where it is held shall not, nor the publication or use elsewhere by any person without the consent and privity of the inventor, be a publication or use so as to prejudice the right of the inventor his executors administrators or assigns to lodge an application for a patent for an invention at any time within *eighteen months* from the opening of the exhibition, nor invalidate a patent that may be granted for the invention. And for the purposes of this section the expression industrial exhibition has the same meaning as in the Industrial Exhibitions Act, 1865: the expression international exhibition has the same meaning as in the Protection of Inventions Act,

*(xiv.)—Fraud. Offences.*

A patent granted to the true inventor shall be invalidated by an application in fraud of the right by provisional protection obtained thereon, any publication or use of the invention contained on that fraudulent application.

If any person makes or causes to be made an entry in the Register of Patents or in the Register of Proprietors, or a writing falsely purporting to be a copy of an entry therein, or procures or causes to be produced or used in evidence any such writing knowing it to be false, or writing to be false, he shall be guilty of an offence.

In each of the following cases, that is to

(1.) If any person writes paints prints moulds casts carves engraves stamps or otherwise marks on anything made used or sold by him in respect whereof he has not a patent, the name or any imitation of the name of any other person who has a patent in respect thereof, without the leave in writing of the patentee;

(2.) If any person, or any such thing, not having been purchased from the patentee or from some person who purchased it from or under the patentee, or not having had the license or consent in writing of the patentee, writes paints prints moulds casts carves engraves stamps or otherwise marks the word Patent or the words Letters Patent, or any words of the like kind or meaning, with a view of imitating or counterfeiting the stamp mark or other device of the patentee, or in any other manner imitates or counterfeits the stamp mark or other device of the patentee;

any such person shall for every such offence be liable to a penalty not exceeding *fifty pounds*, recovered by action or other proceeding or judgment in the High Court of Justice, one-half of to be paid to the Treasury, for the use of the public, and the other to the person who sues.

If any person wilfully and corruptly lodges an application at the Patent-office any such declaration knowing it to be untrue in any material particular, he shall be guilty of a misdemeanour.

*(xv.)—Supplemental as to Procedure.*

43.—(1.) The Commissioners and Examiners may for purposes of this part of this Act administer and take or cause to be administered and taken oaths and declarations:

(2.) If any person in any testimony given on oath or affidavit or in any declaration made under this section wilfully and corruptly makes a statement false in any material particular, he shall be guilty of perjury.

44.—(1.) Notwithstanding anything in this Act, an applicant for a patent may from time to time obtain from the Commissioners, if and as far and on such terms (if any) as the Commissioners think fit, and whether the original period is expired or not, an extension of the period of provisional protection, not exceeding *twelve months* in the whole from the date of the application for the patent.

(2.) In every such case everything done or happening within the extended period shall have effect as if it had been done or had happened within the period originally allowed.

45.—(1.) Where the Commissioners or an Examiner hear an opponent, they or he may if they or he think fit direct by and to whom the costs of the hearing and proceedings connected therewith or any part thereof shall be paid, and how and by whom the amount thereof shall be ascertained.

(2.) If any costs so directed to be paid are not paid within *four days* after service of notice of the amount thereof so ascertained on the party liable to pay the same, the Commissioners may make an order for payment thereof, and that order may be made a rule of the High Court of Justice.

(3.) This section does not extend to empower the Commissioners to direct the costs of opposition to an application for prolongation to be paid by the patentee, in the absence of fraud or misconduct on the part of the patentee.

46.—(1.) An opponent of the grant of or of the amendment of a patent, and an applicant for revocation of a patent, must deliver the prescribed particulars of the objections on which he relies.

(2.) Evidence in proof of an objection of which particulars have not been delivered is not admissible, save by leave of the Examiner or Commissioners hearing the case.

(3.) Particulars delivered may be from time to time amended by leave of the Examiner or Commissioners hearing the case.

47.—(1.) On any opposition to grant of a patent and on any petition for revocation of a patent, the Commissioners may, and on the request of either party shall, obtain the assistance of an expert assessor.

(2.) In appointing an assessor the Commissioners shall have regard to the wishes of the parties, if they agree.

(3.) The duty of an assessor is to give his opinion on any question at the request of the Commissioners, and on any other question which he deems important for the decision of the case, but he has no voice in the decision.

(4.) The remuneration of an assessor may be paid as part of the expenses of the execution of this Act, or by the parties as part of the costs of the proceedings, or partly in one way and partly in the other, as may, subject to general rules, be directed by the Commissioners.

(xvi.)—*Supplemental as to Commissioners.*

48.—The Treasury shall provide an office for the Commissioners called the Patent-office, with a museum and library, and any other buildings that may be requisite for purposes of this Act.

49. There shall be paid out of money provided by Parliament to each Commissioner such yearly salary not exceeding [ ] and to the Examiners such yearly salaries not exceeding in the case of any Examiner [ ] as the Treasury determine.

50.—(1.) The Commissioners may from time to time after the passing of this Act, subject to the approval of the Treasury, appoint so many clerks and officers as they think fit, and may, from time to time remove any of those clerks and officers.

(2.) The salaries of those clerks and officers shall be fixed by the Commissioners subject to the approval of the Treasury, and the same and the current and the incidental expenses of the Commissioners in the execution of this Act shall be paid out of money provided by Parliament.

51. The Commissioners may at any time after the passing of this Act and from time to time (subject to the provisions of this Act) make vary and rescind general rules for prescribing and regulating—

(a.) The form and contents of applications specifications drawings declarations objections certificates reports amendments patents and other documents, and of copies and extracts, and the lodging making recording issuing publishing and inspecting, and otherwise proceeding on and dealing with the same or any of them;

(b.) The evidence and procedure on hearing applications oppositions and petitions for prolongation or revocation;

(c.) The advertisement in a journal to be published periodically by the Commissioners or otherwise, of all matters whereof notice is required to be published by the Commissioners under this Act;

(d.) The keeping of the Register of Patents and of the Register of Proprietors;

(e.) The opening to public inspection, and the publication and sale of copies of specifications drawings models amendments reports and other papers.

(f.) The presentation of copies of the publications of the Commissioners to public libraries and museums, literary and scientific bodies and official authorities, in the United Kingdom and abroad;

(g.) The making printing publishing and selling of indexes to and abridgments of specifications and other documents in the Patent-office;

(h.) The admission of the public to the museum and library provided under this Act;

(i.) The remuneration (subject to the approval of the Treasury) of assessors;

(k.) And generally for prescribing and regulating the management of the Patent-office museum and library, and all things by this Act placed under the direction or control of the Commissioners.

52.—(1.) All general rules made under this Act

by the Commissioners shall as soon as they are made be laid before both Parliament if Parliament be sitting; as if Parliament be not sitting then within four days after the commencement of the next Session.

(2.) If within six weeks of any rule made before Parliament either House resolve that the rule be disallowed, that rule shall be invalid and of no effect, without prejudice to any operation of the rule before the disallowance.

(3.) A rule though made before, does not take effect till after, the passing of this Act.

53. Copies or extracts of or from the Patents and the Register of Proprietors from specifications amendments and objections in the Patent-office, shall, if made on behalf of and sealed with the seal of the Commissioners, be admitted in evidence in any Her Majesty's dominions, and in all places without further proof and without producing the originals.

54. The Commissioners shall cause a statement of the execution by or under them of this Act to be laid annually before both Houses of Parliament, together with an account of the salaries and other moneys received and expended under this Act.

55.—(1.) Not less than two Commissioners shall sit on the hearing of any opposition to or prolongation of a patent, or of an application for revocation of a patent or of any application for the remuneration to be paid by the Treasury for the use of an invention or as to the grant of a patent.

(2.) Not less than two Commissioners shall concur in the making of any general rule for the appointment or removal of any examiner or officer.

(3.) Subject as aforesaid and to any rule of the Commissioners, any power conferred on the Commissioners under this part of this Act may be exercised by any one or more of them:

(4.) Any Act of the Commissioners shall be invalid by reason only of any vacancy in the body or of the power to appoint any Commissioner not having been exercised.

56.—(1.) During a vacancy in the office of Commissioner or the illness or absence of any Commissioner whenever for any other reason the Commissioners deem expedient, an Examiner may be appointed by writing under the hands of two Commissioners to act as and exercise all the powers of a Commissioner under this part of this Act.

(2.) Any such appointment shall be for a period not exceeding six months, but may be renewed.

## PART II.

*Infringement of Patents.*

57. An action or other proceeding for infringement of a patent shall not after the passing of this Act be commenced in any of Her Majesty's Courts of Justice in England.

58. For the purposes of this Act a person shall be deemed to infringe a patent if he copies or in part the invention of a patented article or if he effects the same or a like article without the consent of the proprietor of the patent in a proceeding for infringement.

—(1.) A patentee may complain of any infringement of his patent to the Commissioners.

.) The complaint shall be heard and determined by the Commissioner (other than the legal commissioner) who is best acquainted with the subject-matter of the complaint, assisted by a legal assessor to be appointed for the purpose by the Commissioners.

.) An appeal shall lie from the decision of the assessor thus constituted to the three Commissioners, who shall hear the complaint *de novo*, and their decision shall be final.

.) The Commissioner or Commissioners sitting to hear any complaint may decide all questions of law and fact; they may by themselves or by a person appointed by them enter and inspect any place or thing being the property or under the control of any party to a proceeding before them; they may require the attendance of any person as a witness and the production of books and papers relating to the matter before them; generally they may (subject to the provisions of this Act) exercise all such jurisdiction and powers and make such orders as might have been exercised or made in a like case by any division or judge of the High Court of Justice in England.

.) The pleas allowed by this Act in a proceeding under this Act for infringement of a patent

That the particular matters alleged to be infringed, do not show sufficient invention to justify the grant of a patent, or are not new within the meaning of this Act;

That the patentee is not the true inventor of the invention or of so much of it as is alleged to be infringed;

That the matters complained of do not amount to infringement;

That the claim of the patentee as respects the matters complained of is not stated with sufficient clearness;

That the specification is, as respects the matters complained of, incomplete or misleading.

That the patentee as respects any matter complained of withheld that which he knew to be a better description than that given in the specification.

1.—(1.) In a proceeding for infringement of a patent the complainant must deliver the prescribed particulars of the infringement complained of:

2.) The defendant must deliver the prescribed particulars of objections on which he relies in support of his pleas or plea:

3.) In every case the particulars delivered shall comprise a statement of the places and manner at which the complainant or defendant alleges infringement to have been committed, or the acts and things on which he founds the objections have been done or to have happened, or the action to have been, before the date of the complaint published or used.

4.) At the hearing no evidence shall, except by leave of the Commissioners, be admitted in proof of any alleged infringement or objection of which particulars are not so delivered:

5.) Particulars delivered may be from time to time amended, by leave of the Commissioners.

6.) On taxation of costs regard shall be had

to the particulars delivered by the complainant and by the defendant; and they respectively shall not be allowed any costs in respect of any particular delivered by them unless the same is certified by the Commissioners to have been proven or to have been reasonable and proper, without regard to the general costs of the case.

62. In any proceeding for infringement of a patent the Commissioners may, and on the application of either party shall, obtain the assistance of an expert as assessor; and the provisions of Part I. of this Act relative to experts as assessors (including the provision as to remuneration) shall apply as if they were repeated in this section.

63.—(1.) The Commissioners may at any time after the passing of this Act and from time to time make vary and rescind rules of procedure prescribing and regulating—

(a.) The form nature and service of complaints particulars notices and other documents;

(b.) The period within which anything is to be done in a proceeding for infringement;

(c.) The nature and amount of security for costs to be given by complainants and others;

(d.) Generally the sittings of the Commissioners and the procedure on all matters brought before them under this part of this Act.

(2.) Every rule made under this part of this Act by the Commissioners shall as soon as may be after it is made be laid before both Houses of Parliament if Parliament be sitting; and if Parliament be not sitting then within fourteen days of the commencement of the next Session:

(3.) If within six weeks of any rule being laid before Parliament either House resolve that the same ought to be disallowed, that rule shall be invalid and of no effect, without prejudice nevertheless to any operation of the rule before disallowance:

(4.) A rule though made before, does not in any case take effect till after the commencement of this Act.

64.—(1.) Every person required by the Commissioners to attend as a witness shall be allowed such expenses as would be allowed to a witness attending on subpoena in the High Court of Justice in England.

(2.) In case of dispute as to the amount to be allowed, the same shall be referred to a master of the High Court of Justice, who, on request under the hands of the Commissioners, shall ascertain and certify the proper amount of such expenses.

65.—(1.) Any decision and any order made by the Commissioners under this part of this Act may be made a rule or order of the High Court of Justice, and shall be enforced in like manner as any rule or order of such Court.

(2.) For the purpose of carrying into effect this section general rules and orders may be made by the same authority and in the same manner as general rules and orders may be made with respect to any other proceedings in such Court.

66.—(1.) Where a patent bears on it a statement of the report of an Examiner in accordance with the provisions in that behalf of Part I. of this Act, then in the event of a patentee instituting any proceeding for infringement of the patent he

shall give security for costs of such amount (not being less than *one hundred pounds*) as the Commissioners think fit to order; and if he fails in the proceeding on any ground indicated in the said report he shall pay the costs of the defendant as between solicitor and client.

(2.) Subject as aforesaid the costs of and incidental to any proceedings before the Commissioners under this part of this Act shall be in the discretion of the Commissioners.

67. The costs charges and expenses of and incidental to any proceedings before the Commissioners which are incurred by any person shall if required be taxed in the same manner and by the same persons as if such proceedings were proceedings in the High Court of Justice.

68. This part of this Act does not extend to Scotland Ireland the Channel Islands or the Isle of Man.

### PART III.

#### *General Provisions.*

69. Every document purporting to be signed by the Commissioners or any of them shall be received in evidence without proof of such signature and until the contrary is proved shall be deemed to have been signed and to have been duly executed or issued by the Commissioners.

70. The Public Offices Fees Act, 1866, shall apply to all fees taken in relation to any proceedings before the Commissioners.

Any fee or payment in the nature or lieu of a fee paid in respect of any proceedings before the Commissioners and collected otherwise than by means of stamps shall be paid into the receipt of her Majesty's Exchequer in such manner as the Treasury from time to time direct, and carried to the Consolidated Fund.

71.—(1.) Any notice required or authorised to be given under this Act may be in writing or in print or partly in writing and partly in print, and may be sent by post:

(2.) If sent by post a notice shall be deemed to have been received at the time when the letter containing the same would have been delivered in the ordinary course of the post:

(3.) In proving such sending it shall be sufficient to prove that the letter containing the notice was prepaid and properly addressed and put into a post-office.

### PART IV.

#### *(i.)—Transitory Provisions.*

72.—(1.) Every patent granted before the commencement of this Act, shall have such duration only as it would have had if this Act had not been passed; but as regards the third and the seventh year (if unexpired at the time of the commencement of this Act) of its term it shall, notwithstanding anything in any such patent contained be subject to stamp duties of *Thirty pounds* and *Sixty pounds* respectively and to no others; and the provisions of this Act respecting a certificate of renewal and respecting accident mistake or inadvertence in relation thereto shall also extend to every such patent:

(2.) The provisions of this act relating to the Crown and to the power of the Commissioners to order a patentee to grant licenses shall not extend

to patents granted before the commencement of this Act:

(3.) Any action or other proceeding in a patent pending at the commencement shall be tried and continued in like manner as this Act had not been passed:

(4.) The term of a patent granted at the commencement of this Act may be for any period not exceeding *fourteen years* the Commissioners may see fit:

(5.) In all other respects this Act shall apply to all patents granted before the commencement of this Act in substitution for such enactments which would have applied thereto if this Act had not been passed; and in particular such patents shall be expressly excepted from the operation of the Statute of Monopolies, and shall not be affected by anything therein contained.

73. The Register of Patents and the Register of Proprietors kept under any enactment in force at the commencement of this Act shall respectively be deemed to be the Register of Patents and the Register of Proprietors kept under this Act.

74. All applications for patents pending at the commencement of this Act shall be heard and determined in the interval between the passing and the commencement of this Act, as if this Act had been passed.

75.—(1.) All books documents and other things of every description vested in or under the management of the Commissioners of Patents existing at the commencement of this Act shall immediately on its commencement be under the management of the Corporation constituted by this Act:

(2.) At the same time the staff of clerks and servants of the existing Patent-office shall be transferred to the Patent-office under this Act at the like salaries and on the like terms of offices and places, and with as nearly the like duties as formerly.

76. The repeal of enactments or any part of them in this Act contained shall not—

(a.) affect the past operation of any enactment or the validity of any patent granted, or any compensation payable for anything done or suffered under any of those enactments before or at the commencement of this Act; or

(b.) interfere with the prosecution of any action or proceeding civil or criminal commenced before the commencement of this Act or thereafter; or

(c.) take away or abridge any privilege or benefit in relation to any such proceeding.

#### *(iii.)—Transfer of powers as to Registration of Trade Marks and Copyright of Designs.*

77. All powers duties and authorities imposed on or exercisable by the Commissioners of Patents under the Acts relating to the Registration of Trade Marks, and the Acts relating to Copyright of Designs, are hereby transferred to and imposed on the Commissioners constituted by this Act; and those Acts shall have effect accordingly.

(iii.)—*Scotland.*

nalty under this Act in respect of the  
ed use of a name word stamp mark or  
' be recovered in Scotland by action or  
eeding or information in the Court of

order of the Commissioners for payment  
ay be recorded in the books of Council  
n in Scotland to the effect that execution  
hereupon in common form.

(iv.)—*Ireland.*

withstanding anything in this Act, all  
ll have in Ireland their remedies under  
st of a patent as if it had been granted  
o Ireland only.

(v.)—*Saving for Crown.*

81. Notwithstanding anything in this Act, it  
shall be lawful for her Majesty the Queen, her  
heirs or successors, by warrant under the Royal  
Sign Manual—

To direct any specification to be cancelled be-  
fore the sealing of the patent, and there-  
upon the provisional protection shall cease :

To direct the Commissioners to refuse the  
sealing or issue of a patent :

To direct the insertion in any patent of any  
restrictions, conditions, or provisos.

82. Nothing in this Act shall take away, abridge,  
or prejudicially affect the prerogative of the Crown  
in relation to the granting of any letters patent,  
or to the withholding of a grant thereof.

## THE FIRST SCHEDULE.

## PART I.

*Acts partly repealed.*

and Chapter.	Title or Short Title.	Extent of Repeal.
c. 3. of Monopolies]	An Act concerning Monopolies and Dispensations of Penal Laws and the Forfeiture thereof.	Section six.
c. 69.	An Act for Amending an Act passed in the fourth year of the reign of his late Majesty, intituled an Act for the better Administration of Justice in his Majesty's Privy Council, and to extend its jurisdiction and powers.	Sections two to five, both inclusive.
t. c. 3.	The Industrial Exhibition Act, 1865.	Section three.
t. c. 27.	The Protection of Inventions Act, 1870.	Section two.

## PART II.

*Acts wholly repealed.*

and Chapter.	Title or Short Title.
IV. c. 83.	An Act to amend the Law touching Letters Patent for Inventions.
c. 67.	An Act to Amend an Act of the fifth and sixth years of the reign of King William the Fourth, intituled An Act to amend the Law touching Letters Patent for Inventions.
t. c. 8g.	The Patent Law Amendment Act, 1852.
t. c. 5.	An Act to substitute Stamp Duties for Fees on passing Letters Patent for Inventions, and to provide for the purchase for the public use of certain Indexes of Specifications.
t. c. 115.	An Act to amend certain provisions of the Patent Law Amendment Act, 1852, in respect of the transmission of certified copies of Letters Patent and specifications to certain offices in Edinburgh and Dublin, and otherwise to amend the said Act.
13.	An Act to amend the Law concerning Patents for Inventions with respect to Inventions for Improvements in Instruments and Munitions of War.

## THE SECOND SCHEDULE.

*Form of Letters Patent.*

, by the grace of God, of the United Kingdom  
of Britain and Ireland, Queen, Defender of the  
faith, to all to whom these presents shall come

A. B. hath by his petition humbly repre-  
sented that he is in possession of an invention  
the nature of which is described in the specification annexed

hereto, and the petitioner hath also represented to us  
that the said invention will be useful to the public,  
that he is the true inventor thereof, and that the same  
is not in use by any other person to the best of his  
knowledge and belief :

And whereas the petitioner hath humbly prayed that  
we would be graciously pleased to grant unto him  
(hereinafter together with his executors, administrators,  
and assigns, or any of them referred to as the said  
patentee) our Royal Letters Patent for the sole use and  
advantage of his said invention within our United

Kingdom of Great Britain and Ireland, the Channel Islands, and Isle of Man.

And whereas we being willing to encourage all inventions which may be for the public good, are graciously pleased to condescend to the petitioner's request:

Know ye, therefore, that we, of our especial grace, certain knowledge, and mere motion do these presents, for us, our heirs and successors, give and grant unto the said patentee our especial licence and full power and sole privilege, that the said patentee by himself his agents or licensees and no others may at all times hereafter during the term of years herein mentioned make use exercise and vend his said invention within our United Kingdom of Great Britain and Ireland the Channel Islands and Isle of Man in such manner as to him may seem meet and that the said patentee shall have and enjoy the whole profit and advantage from time to time accruing by reason of the said invention during the term of years herein mentioned; To hold exercise and enjoy the said licence powers and privileges unto the said patentee during the term of *seven* years from the day of : And to the end that the said patentee may have and enjoy the sole use and exercise and the full benefit of the said invention we do by these presents for us our heirs and successors strictly command all our subjects whatsoever within our United Kingdom of Great Britain and Ireland the Channel Islands and the Isle of Man that they do not at any time during the continuance of the said term of *seven* years either directly or indirectly make use or put in practice the said invention or any part of the same nor in any wise imitate the same nor make or cause to be made any addition thereto or subtraction therefrom whereby to pretend themselves the inventors thereof without the consent licence or agreement of the said patentee in writing under his hand and seal on pain of incurring such penalties as may be justly inflicted on such offenders for their contempt of this our Royal command and of being answerable to the patentee according to law for his damages thereby occasioned: Provided that these our letters patent are liable to be revoked on the grounds and in the manner from time to time by law provided: Provided also that if the said patentee shall not pay all stamp duties by law required to be paid in respect of the grant of these letters patent or in respect of any matter relating thereto at the time or times and in manner for the time being by law provided and also if the said patentee shall not supply or cause to be supplied for our naval or military service all such articles of the said invention as may be required by the officers or Commissioners administering any department of those services respectively in such manner at such time and at and upon such reasonable prices and terms as shall be settled in manner for the time being by law provided that then and in any of the said cases these our letters patent and all privileges and advantages whatever hereby granted shall determine and become void notwithstanding anything hereinbefore contained: But nothing herein contained shall prevent the granting of licences in such manner and for such considerations as they may by law be granted: And lastly, we do by these presents for us our heirs and successors grant unto the said patentee that these our Letters Patent shall be construed in the most beneficial sense for the advantage of the said patentee. In witness whereof we have caused these our letters to be made patent this

One  
Thousand Eight Hundred and in the  
year of our reign and to be sealed as of the said  
One Thousand Eight Hundred and  
By Order

*Specification.*

To all to whom these presents shall come:  
I, A. B., of send greeting:

\* Whereas I the said A. B., on the day of lodged in the Patent-office a provisional specification of the invention herein mentioned and applied for of a patent for my said invention unto me the A. B., my executors administrators and assigns know ye that I the said A. B. do hereby declare the nature of my said invention and in what manner the same is to be performed to be particularly described and by the following statement (that is to say,)

[Describe the Invention.]

In witness whereof I have hereunto set my hand and seal this day of A.D.

\* NOTE.—If no provisional specification was lodged will run:—Whereas I the said A. B., on the day of applied for a grant of a patent for the invention herein unto me, &c.

### THE THIRD SCHEDULE.

#### Stamp Duties.

On application .....  
On grant of patent .....  
On expiration of 4th year of patent .....  
On expiration of 8th year of patent .....  
On application to amend specification .....  
On order giving leave to amend .....  
Prolongation of patent—for each year of prolongation .....  
On certificate of record of notice of appeal against decision of Examiner .....  
On certificate of record of notice of opposition to any application .....

### CANTOR LECTURES.

#### WATCHMAKING,

By Edward Rigg, M.A.

#### LECTURE III.—DELIVERED MONDAY, FEB

*Necessity of efforts to promote the art in the*  
—Need of education, theoretical and practical  
horology—Literature—Great want of it  
in gauges, screws, &c.—Exhibition of  
and complicated watches, and of watch  
tools—Conclusion.

The published syllabus of this third lecture me feel very strongly that some explanation as far as possible, justification of the matter therein mentioned is due to my more especially when the technical character of the last lecture is borne in mind. But, regarding the object with which this Society originally formed, and which it has for a and a quarter steadily kept in view, the progress of arts, manufactures, and commerce, I find some grounds for hoping that those who seriously thought of the condition of the horology art in this country will admit that I have fairly have taken a very different course. Watchmaking is an art in a very high sense of the word, and, in addition to being of universal interest, is well deserving of scientific investigation from the fact that it brings the worker in relation with many abstract physical

pe any other branch of mechanics; and it is extravagant to hope that it will in the future us to a fuller knowledge of them. And yet amount of attention it has received from men ence has been very small, especially in this ry. Most of its truths have been arrived at, y scientific reasoning, but by pure experiment observation, and most of the treatises on gy consist rather of statements of facts and ptions of apparatus than of any logical train ument. One consequence of this is that the great ity of those engaged in the art regard science no way a concern of theirs, and, as Saunier ointed out, are not unfrequently ready to offence at any suggestion that they could t by a knowledge of it. As an instance of ake the case of the best form of teeth of s. No mechanician doubts the advantages cycloidal or involute teeth, but how often is hmaker found to believe in them as bearing trade? He knows that if his cutter is of a hich experience has shown to be satisfactory, good depth may be secured, but he ignores t that this vaunted experience has only led, or less accurately, to the discovery of one r of those forms that were proved by matical investigation to be the best more century ago.

le the industry would have materially ed in the past by the aid that science had r, a specially adapted scientific training is han ever necessary to its well-being in the . In face of the eager competition by which sailed at the present day, we may be certain cannot remain stationary, and if there is od evidence to show that advance is made, y safely conclude that it is in a decaying

not only is all knowledge of science omitted le training of the watchmaker; now-a-days, le manual skill is in great part wanting, and general complaint that no sufficient supply petent young workmen is to be found to be place of the older men; indeed, I am d that practically the whole of the best work kenwell is now performed by men advanced rs. This has resulted from the failure of the stem of apprenticeship and the neglect to le a substitute, a change in our social con- which has more than once been discussed in com.

of two results must necessarily follow from state of things, and that very shortly: stic steps must be taken to provide for the tion, both theoretical and practical, of our young workmen, or the quality of est English work must rapidly deteriorate. this urgent need of technical education has rood itself upon the attention of every watch- ng community, those on the Continent, already sion of schools, doing all in their power ance their utility and increase their number, America, notwithstanding the minute tion of its machinery, is fully alive to their ty.

terland already possesses six such schools, ny two, and France three, that of Paris g only been opened on the 6th of March in cent year. As showing how its importance tantly borne in mind by the watchmakers

of that city, I would mention that for seven years a subscription list has been open for the purpose of establishing a school of watchmaking, and their private exertions have at length secured a sum sufficient both for the establishing and maintenance of such a school.

In England, however, the special instruction hitherto available for watchmakers has been very slight, consisting mainly of drawing classes and occasional lectures on technical subjects at the Horological Institute. But in the early part of last year very important additions were made to the instruction there given, through the liberality of the City and Guilds of London Institute for the Promotion of Technical Education; and, thanks to them, we now possess a horological school whose immediate future must have a marked influence on the progress of English watchmaking, and will be looked to with no little interest by all who desire the art to prosper in this country. Indeed, I think it has a wider interest. Technical instruction has for many years had its eager advocates, among whom I may be permitted to mention my late father as having been the first to organise, 35 years ago, classes for the teaching of various trades, such as carpentry, mechanical engineering, printing, bookbinding, glass staining, &c., at Chester; but never was public attention so thoroughly directed to its necessity as it is at the present day. This school of horology is one of the first founded by the City Guilds Institute, and I doubt whether they could have selected a trade more suitable for the purpose of demonstrating the practicability of technical education among us. For the experiment can be made efficiently without the purchase of a very elaborate plant, theoretical and practical instruction can easily be carried on side by side, and the student can be placed in conditions similar to those in which he will find himself in after life. A further recommendation consists in the fact, that the scheme admits of a gradual extension, so as ultimately to include all the allied branches of the trade, such as dial and case-making and engraving, as well as to clock and chronometer making, and to that most important but sadly neglected branch, tool making. At the same time a rapid advance must not be looked for, for the art is of such a character as to require a special preliminary training of the pupils, so that the more or less complete want of this instruction will render their progress proportionately slow.

The school has existed since the summer of last year. In addition to the various branches of the art to which the pupils devote four full days a week, there are classes and lectures for instruction in the elementary principles of physics and mechanics that have a bearing on horology. It is gratifying to observe that all the benches at present available for practical pupils are occupied, and the progress they have hitherto made justifies a hope that the experiment will prove to be in every way successful. Systematic instruction has been one of the urgent wants of the watchmakers of this country for at least half a century; with the powerful support of the City Guilds they now have an opportunity, such as many of the continental centres of the industry may well envy, and it is for them to see that the most active encouragement is given to the experiment. In the

face of a steady depression in trade, the English watchmakers have, with most praiseworthy efforts, erected a Horological Institute; it remains for them to continue their exertions, in order to ensure success in the application of that Institute to its legitimate uses.

On one point I would venture to make a special appeal. The practical classes are necessarily limited in number by the space available, and although it is earnestly to be hoped that means may, ere long, be found to increase the accommodation, they must always be, in a sense, inelastic. But this is not the case with the lectures or theoretical classes, and if those actually engaged in the trade could, as a body, be brought to perceive that a scientific knowledge of their art is often even more essential than manual skill as a means of securing real progress, all the more so because the art is already in a highly advanced state, the theoretical instruction provided would not be confined, as it now is, entirely to the practical students. The Technological Examinations of the City Guilds Institute—examinations which have for many years been carried on, in various trades, with such signal success by this Society—may be expected to form an additional inducement to the younger members of the trade to join these or other similar classes, even although it involves the devotion of a few of their working hours to study. The prizes, medals, and certificates will constitute guarantees of a certain amount of theoretical knowledge such as have never existed in this country before, and it is not too much to expect that the higher standard of education to be secured by these means will immensely facilitate the introduction of some of the other improvements to which reference has already been made.

As the reduction in the number of men competent to undertake high-class work may be traced to the gradual failure of the old apprenticeship system, so the general lowness in the standard of theoretical knowledge is undoubtedly in great part due to the want of a special literature. It is simply incredible that English horology should have attained the eminence it certainly has attained without possessing a single treatise that could pretend to be even approximately complete. A partial exception should, perhaps, be made on behalf of Thomas Reid's volume, "On Clock and Watchmaking," published in 1826, but he directed his attention mainly to clockmaking. There are, of course, trade journals, &c., but the watch and chronometer may be said to have been ignored except in such volumes as those of Harrison, Mudge, Earnshaw, and others who had special inventions of their own to describe. And this may, perhaps, help to account for the neglect of the subject by the public, notwithstanding a few small treatises written for their edification. As I incidentally observed in the first lecture, France is exceptionally well supplied in this respect, as witness the elaborate works of Thiont, Berthoud, Lepaute, Dubois, Moinet, the more recent "Traité d'Horlogerie Moderne" of M. Saunier, and the many profound investigations into the theory and use of the marine chronometer, which were lately published, in a collected form, by M. Lédieu, in a work on the "New Methods of Navigation." M. Saunier's work, thoroughly practical, and, at the same time, constituting a scientific discussion

of the principles involved in watchmaking as had not previously been attempted, recognised text-book in use in all the horological schools of the Continent, and I am amply enough to trust that the translation of it, by Mr. Tripplin and myself have recently completed, will be of service to the art in this country as an instrument of education and a reference, and as a means of reviving interest in the subject. Several works of utmost value to the art have come from the M. Saunier, notably the *Revue Chronométrique* now in its twenty-ninth year of publication we hope, before the end of the present year, complete the translation of another volume by the same author, "The Watch Handbook," which is of a more purely practical character, and calculated to afford assistance in the daily work of watchmaking and repairing.

A brief reference was made at the end of the lecture to the question of standard sizes. Every step is taken with a view to establish the English trade on a firmer footing, and it is questionable that the systems of measurement must come in for an important share of attention. Various efforts at reform have been made during the last half century, but with no result, and the late Charles Frodsham, in pretending but remarkably useful little volume of 40 pages, entitled, "A Few Facts Concerning the Elements of Clock and Watchmaking," in 1862, threw out a number of important suggestions on the point, which, I believe, have received but little attention. The present system, if system it can be well illustrated by his account of the movement gauge. He experienced considerable difficulty in discovering the scale by which the well-known numbers used to designate the thickness of the plates are related, and concludes that they represent successive additions of thirtieths of an inch to the thickness of the plate, which is called 0, with a constant addition of  $\frac{1}{30}$ th inch for the "fall," or room to allow for the plates to open and shut in the case. A 16-size watch will have a diameter of 1-10 or 1-7 inches, which obviously is quite unconnected with the gauge number, unless the thickness of the plates happens to be known; and, I would add, the amount is not a constant, for different makers employ slightly different gauges, thus it happens that almost every movement requires a case and dial to be specially made. The graduation of the pillar gauge, by which the distance between the two plates of the movement is measured, is even more complex. The thickness of the plates is pressed by the utterly meaningless combination of  $\frac{1}{30}$ th inch is called 0, and  $\frac{2}{30}$  is equal to 1, &c.

In place of all this gratuitous confusion, it is proposed to adopt a system of measurement by decims of an inch for all parts of the movement, and it is to be desired that some such modification should be introduced when the reforms in the watchmaking which are so urgently needed are effected. I would be travelling beyond my present point to enter into this question of gauges, but it is well deserved discussion, and it would be to take full advantage of any system that has received the cordial support of the Society. [A very complete collection of the gauges

makers, most of which had been lent by Grimshaw and Baxter, was exhibited, and of uniformity in their systems of graduation. Sets of standard gauges that I at 1/16th inch and differed by 1/16th inch also kindly lent by Sir Joseph Whit-

the gauges in ordinary use, such as the gauge and the main-spring gauge, are on an easily intelligible system, and, as foreign manufacture, their basis is in cases the millimetre. They are cheap, accurate for the purposes for which intended, and as a large number of used by the generality of watchmakers of continental origin, it seems all but that the inch can be established as a gauge in the trade, but a double graduation on gauges is all that would be required to watchmakers to work on either system, as this might render necessary.

The Society of Arts of Geneva has recently decided this question of gauges as well as this closely allied subject, the threads of which they have proposed certain standards. Swiss manufacturers seem disposed to it is to be hoped that English makers may agree to introduce the same standards, at least so far as they are brought in contact with continental trade.

Twentieth standards afford an invaluable aid in watchmaking, and when the manufacturers movement makers have come to an agreement to work rigidly to them, a very improvement will have been taken towards the uniformity of the English trade. There are departments of the manufacture that are, however, self-contained, and do not directly contact with the gauges in use on the watch, and for them the value of these standards is over-estimated. As bearing on this subject I must not omit to mention that the Department of the Board of Trade has made arrangements by which great facilities are offered for verifying gauges of all sizes in this system, having procured a complete set of standards comprising all dimensions from 1/16th inch to six inches. This should constitute a strong reason for watchmakers taking to organise their systems of measurement, but one other point to which I desire to refer before proceeding to exhibit, is the use of the electric lamp, a number of various degrees of complexity, which a number of friends has enabled me to collect for evening.

My collection of tools, for the loan of which I am indebted, as was the case with the tools to Messrs. Grimshaw and Baxter, was primarily, to show the types of tool that a watchmaker or manufacturer on the Continent employs. It will be seen at once that the tools entirely in design from the machines used by other workers in metal, and often the devices used are radically different. The objection as this is, of course, not likely to be met with novelty to watchmakers, but it is of great value to examination by all who are engaged in mechanical work, as many of the present special features that might

with advantage be adopted in larger machines. [As examples, mention was made of the pump centre of a mandril, by which almost any piece can be centred with the utmost facility, and the depth tool used in the clock, chronometer, and watch trades for determining the positions of pivot holes, so that wheels and pinions should run smoothly together. A number of the tools were briefly explained, and their special features as compared with those used in other mechanical arts were pointed out. The attention of watchmakers was also drawn to the beautiful series of tools manufactured by M. G. Boley, of Esslingen, Wurtemberg, some of which were exhibited.]

And I had another object in bringing these tools here this evening. I want to draw attention to the very great interest that watchmaking possesses for those that amuse themselves with mechanical pursuits; and, without in any way wishing to decry that most perfect tool, the lathe of, say, four or five inch centre, the usefulness of which, indeed, it would be difficult to over-estimate, I feel very strongly that its smaller relatives have hitherto been too much neglected by amateurs. The tools employed in watchmaking can be obtained at comparatively moderate cost, and lend themselves to great variety of operations on a small scale. They occupy but little room, and, although of course I am far from pretending that amateur mechanics could actually make a watch, I can positively say from experience that, if they would interest themselves more in the subject, they would derive a great amount of pleasure, even from the mere cleaning of a common watch, and the higher branches of the art are naturally more attractive. In England it has hitherto been kept far too much to itself, and the sympathy with its advance which the interest of amateurs would develop could hardly fail to benefit the trade generally. On the Continent its advantage was long ago recognised; thus in 1860, an eloquent article appeared in the *Revue Chronométrique*, from the pen of M. Philippe, of Geneva, "On the necessity for some remedy to arrest the decline of Horology," in which reference was made to this question. He says:—

"If the attention of the public was more frequently directed to our work, if they were more initiated into the difficulties of the art and its scientific aspects, we might succeed in creating a band of amateurs such as formerly existed, such as still exists in all the arts and very many of the sciences . . . to the advantage of those high-class workers, whose energy and whose talents would often be discouraged without such support."

In the preceding lecture I have referred to the urgent necessity of reform in the tools used in watchmaking; while this primarily had reference to the more extended use of machine tools, it is in a less degree applicable to the smaller instruments used by the maker or repairer. England formerly manufactured her own, but now most of the tools in use are of Swiss construction. And yet Prescott still possesses makers unsurpassed in manual skill by any in Switzerland, and would, doubtless, possess many more, were it not for the fact that the trade was long ago crippled by the underselling of their competitors. They seem to suffer from the same failing as is only too noticeable in other branches of the trade, want of "life," which

is apparently nourished by an unfounded feeling that watchmaking cannot aspire to be a national industry.

This inactivity is, after all, more responsible for the present depression than any deficiency of tools, and, in evidence of this, I would quote the case of Besançon. There, the system of manufacture is essentially the same as ours. The tools employed are similar, machinery being only applied, as at Prescott, to the movement-making. But, while our trade is contracting, theirs is expanding at a remarkable rate. Thus, in the five years 1845-9, the official returns show that the Besançon district completed 239,323 watches, of which 16 per cent. were gold. The out-turn has been steadily increasing since that period, and in one year, 1878, no less than 454,886 were manufactured, nearly double the number given for the above period of five years, and the per-centage of gold cases rose to 32.

Yet, in face of this expansion, which has continued through a period of universal depression in trade, the Besançon manufacturers are keenly alive to the necessity of extending the use of machine-tools. Their success is mainly due to the possession of that essential quality—energy; and they are further supported by the conviction that watchmaking is a national industry. I am far from denying that, in this country, there are many keenly alive to the necessity of radical changes, but individual exertion is not sufficient, and no collective action has yet been taken by the manufacturers.

[The lecturer then proceeded to exhibit a number of watches, projecting them on to the screen by the aid of the electric lamp. The collection comprised many varieties of keyless watch, quarter, half-quarter, and minute repeaters, stop-watches, minute and split-seconds chronographs, pedometer and calendar watches, mechanical and musical watches, antique watches, blind man's watch, &c. He expressed his indebtedness to the undermentioned gentlemen and firms, who had kindly lent them for exhibition—Dr. Longton, Southport, for a collection of 24 watches; Messrs. Lund and Hockley; Messrs. Patek, Philippe and Co.; Messrs. Guye; Mr. Glasgow; Herr Von Lohr, Mr. Tripplin.]

And here I must bring this course of lectures to a conclusion. It remains, however, for me to thank most sincerely those many friends whose liberal assistance has enabled me to exhibit these valuable watches, as well as the tools, gauges, and parts of watches at this and the preceding lectures. It is no small privilege to be entrusted with such a collection as that lent me by Dr. Longton, of Southport, and I am sure that his kindness as well as that of others, whose names I have mentioned, will be as much appreciated by you as it is by me. The assistance I have received from various members of the trade has been very great, and if I have been so fortunate as to interest any of my audience in the progress of the art in this country, it has been in great part owing to the specimens and information with which they have always most readily supplied me. And I must not omit to acknowledge the valuable aid I have received from Mr. S. G. Willmott, who has prepared these beautiful diagrams.

Looking back at the ground over which we have

gone, I cannot help feeling how many points been either ignored, or barely referred to, the nevertheless of the highest importance. But that questions of a theoretical or merely descriptive nature, if discussed with sufficient fulness, would extend over far more than three lectures, and such points as those to which I have drawn attention are so much in need of consideration, I might count on your indulgence in treating watchmaking in a manner somewhat different from what is generally expected in a Cantor. It is very seldom that the art is brought to the public at all; and I therefore feel the honour in being allowed to urge its claim attention in the room of this Society.

There are many reasons why reforms introduced into the system of manufacture would now have a better chance of being successful. We confidently look forward to the technical instruction of our young watchmakers improving. Foreign competition is forcing itself more and more on our notice, and the literature of the art has received important additions. If, then, of our most prominent horologists at the centres of the industry, would jointly consider the many questions that need solution—the calliper, the gauge, and the system of manufacture—and if the several branches of the art would cordially work together for the good, we might look with confidence for a marked improvement in the official returns in the future. The cheaper class of English watches gradually shake off the discredit that has often to hang over it, and might compete on some chance of success with those of foreign construction, at any rate, in our own country.

## MISCELLANEOUS.

### EDUCATION REPORT, 1880.

The report of the Committee of Council on Education just issued, has formed the text of a leader in the *Times* from which it appears that the following are the chief results. While the schools inspected in 1879 numbered only 8,281 in number, in 1880, after but ten years elapsed, they numbered 17,743. In the former year accommodation was provided for less than two millions of children; now there is accommodation for 3 millions and a quarter. The average attendance in 1870 was 1,162,389; last year it was 2,750, an increase of a hundred and fifty per cent. This is not to be set down solely to the Board schools. Voluntary schools have at least kept pace with the State. While in the year of the Act there were but 8,300 voluntary schools inspected, these had increased to 11,180, the total number of the Board schools being only 8,433, and the numbers of children in all the voluntary schools bearing to those in the Board schools a proportion of about five to two. The last inspection showed an improvement not only in the numbers of children, but in the quality of the instruction. In the case of "specific" subjects, in which the grant depends on the proficiency shown by the children, and which are open to children who have not passed the fourth standard, 160,323 offered themselves for examination, and 478,761 presented in that standard, and of these 478,761 presented, the favourite subjects were English, animal physiology, physical geography, household management, or domestic economy.

Taking the large schools with the small, and

the help given by pupil-teachers, about onested master or mistress for every hundred is assumed to be a fair allowance, so that if 00 is to be taken as the full number who ought receiving elementary instruction in England and the teachers should number about 35,000. The number now existing is 31,422, who are mainly id by the training colleges, such as those at ea and Culham. Mr. Sharpe, the Inspector of leges for Masters, says that the training colleges t supply the demand for the poorer classes of ; they practically supply the demand for schools an afford to pay about £100 a year for head or t teachers." Out of some 13,000 masters, there 00 who are earning more than £200 a year, with out of 8,000 mistresses there are nearly 300 the same. More important is the general which is thus stated in the report:—"The salary of a certificated master, which in 1870 12s. 9d., is now £127 2s. 7d.; that of a school- was £57 16s. 5d. in 1870, and is now £72 ." About a third of the whole number are d with residences rent free. Whereas out of ards established in boroughs, only 21 have ompulsory, to meet a deficiency in school odation, in the case of unincorporated towns ral districts no fewer than 1,000 out of Boards have been established by order of partment. The area under "compulsory ce bye-laws" has been steadily increasing, hile, in 1872, a population of eight millions that was included, the population subject to s is now, including that under School Attend- mmittees as well as that under Boards, more- enty-two millions. In the voluntary school a sts in London about £2 a year to educate; else- from 30s. to 36s. In the Board school he costs on about 57s.; elsewhere, from 28s. (in Hull) to Bradford). He earns from 15s. to 17s. from ernment grant. He pays from 8s. to 15s. in ence; in the voluntary schools the subscriptions, ke out the expenses, amount to an average of ad, and in the Board schools the amount con- by rates amount to sums which vary from in Hull to 33s. 7d. per child in London, the being about 15s. Taking the whole amount elementary education, it appears that the sum ted by voluntary subscribers is almost exactly o that levied by rate—£739,155 as compared 26,226; and that both added together amounts et exactly the total contributed by fees—viz., 828. The total Government grant amounted r to £2,130,009.

## NOTES ON AMERICAN SCIENCE AND MECHANISM.

### NEW THEORY CONCERNING BOILER EXPLOSIONS.

able-bodied individual, Mr. D. T. Lawson, of rg, Pennsylvania, has just succeeded in affording the solution of a problem that, up to the time, is believed to have baffled engineers, viz., e of the bursting of steam-boilers under certain stances. Repeated attempts had been made both Government and private auspices to burst a ntentionally with the terrific force known in such tion to spread havoc far and wide, but all such s had failed, the collapse of a flue having been t that was attained. But an explosion has at been obtained on a scale so grand as to blow the nto fragments, which were scattered all over the n which the experiment was made. This boiler dilt of the very best materials expressly for this nd was constructed in the best possible manner. o'clock the fire was started, and at five o'clock ing was ripe for the experiment. The boiler, was six feet in length by thirty inches in diameter,

was all that time three-fourths full of water, which was seven or eight inches above the fire-line, and the steam-gauge showed a pressure of 380 pounds to the square inch, the tensile strength of the boiler being 604 pounds to the inch. The spectators having retreated to the bomb-proof sheds erected by the Government, by the agency of a string the valve was pulled, and a full head of steam let into the cylinder. This was attended by an explosion so terrific that the earth shook as if by an earthquake, and when, a few seconds afterwards, the shower of *debris* had somewhat passed, and an examination made, everything was found to have been completely demolished and torn into fragments, some of which were found over half-a-mile away from the scene, others being projected to a greater distance.

The theory that was sought, and is believed by Mr. Lawson to have been established by the experiment narrated, is as follows:—"Superheated water" is the only explosive element in a steam boiler, and when highly superheated, it is as explosive as gunpowder, but it does not explode from the same cause nor in the same manner. Gunpowder explodes by chemical union, upon ignition, the explosion being accompanied by a visible flash. Superheated water explodes, on a sudden reduction of the pressure from its surface, by bursting into steam, which instantly fills over 1,700 times the space occupied by the water. An explosion, therefore, only takes place after the engineer has opened the port and allowed a small portion of the steam to escape into the cylinder, creating a vacuum to that extent over the superheated water, a portion of which instantly bursts into steam, striking every square inch of the boiler with a concussive force many times greater than the regular pressure of steam. The numerous explosions which takes place just as steam is turned into the cylinder at starting are claimed by Mr. Lawson to corroborate his theory.

By suddenly injecting cold water into a boiler of superheated water an explosion will, on the same principles, be caused. The fact of explosions occurring under such circumstances has long been recognised, but in the estimation of many they were supposed to be caused by the cold water coming into contact with the heated iron of the boiler—an hypothesis Mr. Lawson claims is no longer tenable, for viewed in the light of his experiment the cold water would, merely by condensing the steam in the boiler and withdrawing the pressure upon the superheated water, favour the expansion of the latter into steam possessing a greater degree of pressure than any ordinary boiler could stand. Another experiment is soon to be made with a boiler tested under similar conditions, but which it is believed will not burst. In it the means of safety are found in constructing a partition to intervene between the flues and the top of the boiler, thus creating a steam compartment over the water compartment, to be supplied with steam evoked from the water through valves in the partition, and which valves are smaller in the aggregate than the part through which the cylinder is fed from the steam compartment.

The Glasgow readers of this *Journal* will probably recollect of an explosion that took place on board of a new and very quick passage steamer—the *Telegraph*, I think, although I have no means at present of verifying this—over thirty years ago. She stayed at a pier down the Clyde for a short period to land passengers, and no sooner was steam admitted to the cylinders to start her, than the boiler exploded with great violence. Numerous theories were hazarded by scientific men at the time to account for the explosion, that which was considered most tenable being the decomposition of the water or steam into its elementary gases by contact with the red-hot plates of the boiler) which also served to ignite the gases (oxy-hydrogen, thus formed. The new theory of Mr. Lawson as to explosions appears to me to meet this case, and explain it in a more satisfactory manner.

#### DETERMINATION OF THE HEATING POWER OF THE SUN, AND OF THE COLOUR OF ITS LIGHT.

A party of scientific men have just started upon an expedition of a novel nature. The enterprise has for one of its objects the ascertaining whether the real colour of the sun be not blue, although its main object is to determine by actual experiment the amount of heat given by the sun to the earth. One of the most elevated summits on this Continent in an extremely arid region being essential, the expedition will proceed to the neighbourhood of Southern California or Arizona. It is well known that the chief of the expedition, Prof. S. P. Langley, Director of the Allegheny Observatory, who has acquired a reputation in connection with solar physics, firmly holds that the sun is neither white, yellow, nor red, but of a "deep, dark, beautiful blue," the colour being modified to its usual appearance by its passage through the atmosphere. The value of the inquiry is found in the fact, that if our atmosphere has played the part of an obstructor and modifier of the real colour of solar rays, an enormous proportion of the sun's heat has not been taken into account in those questions of scientific meteorology which have a special bearing on climate.

#### A TORNADO OF UNUSUAL VIOLENCE.

At almost every hour during these two days are telegrams and letters pouring in, giving an account of one of the most fearful tornadoes which has ever visited the United States, and by which an entire city has been nearly swept out of existence. The force and fury of the storms in the "Far West" are well recognised as matters of frequent occurrence; but nothing, fortunately, for many years, has occurred at all to be compared with that which, three days ago, and in the course of a few minutes, almost obliterated the thriving little city of New Ulm, Minnesota. Many have been killed, a much greater number injured, a still greater number quite ruined, so far as concerns worldly goods. Pending the arrival of the reports from the scientific men and newspaper correspondents, who have started off to visit the scene of this tornado, the few following facts may be accepted as correct.—At twelve minutes to five o'clock in the afternoon of the 15th inst., a dark cloud, which had been seen approaching rapidly from the north-west, engulfed the city, which, at the same instant, was struck by a cyclone that in two minutes had levelled churches and many houses. Total darkness supervened, the noise of the tempest being appalling, especially added to the shrieks of women and the shouts of men, as houses were being thrown down, and their roofs sent flying through the air. After a minute or two a lull ensued, and people began to breathe more freely, when all of a sudden the fated city was struck with greater violence than before by the storm from a nearly opposite direction, and this completed the work of devastation. At two minutes to five the fury of the storm had subsided, but during the ten minutes that it lasted it was shown how active could be the forces of nature. One man describes how, when speaking to his wife, he found himself suddenly being carried through the air a distance of some hundred feet. The head of a well-known young lady, who is believed to have been struck by a piece of timber, was afterwards found on a prairie some distance away, and far from her body. The head of another lady was found at a distance of a tenth of a mile from her body. One child was carried over half a mile, and still lives. Many horses were killed, some having been lifted bodily through the air. Some framed houses have been carried away to such a distance, that no traces of them have yet been found. During the storm the lightnings were playing incessantly, and but for them the city would have been as dark as at midnight, for the fires, which continually were being kindled, could not spring into activity, on account of the torrents of rain. Some little time will have elapsed yet, ere the data are obtained

on which to write, in a scientific manner, of this dreadful visitation. New Ulm is owned, and occupied by Germans. The most terrible history was its destruction during the Indian on the 19th of August, 1862. Since that it has grown and prospered, the Indians having been finally defeated. The scientific aspect of the visitation will be interesting, as it is so seldom that such violence occurs in the northern hemisphere.

New York, July 18th, 1881.

#### GENERAL NOTES.

**The Telephone in London.**—The United Company state that they have now in London 1,000 subscribers, and that the "calls" average 100 per subscriber. It is also announced that the company have at the Post-office to connect three of their exchanges with the Postal Telegraph Department at St. Martin's-le-Grand, so that messages can be handed to non-subscribers at a place of business within a short radius of the Post-office for a charge of 3d. per twenty words, or they will be sent anywhere in the United Kingdom at the usual telegraph rates. The list of subscribers to the "Exchange" includes the Society of Arts.

**Ceylon Pearls.**—The Ceylon pearl fishery is languishing, and a correspondent of *Observer* reports that a new bank has been discovered from which are of a larger size than those hitherto known at this fishery. The prices have run up from 1s. 6d. and if it is found practicable to extend the fishery there is a great probability of the total amount of the Government reaching £75,000, thus exceeding the amount of 1859 (£48,000) and 1863 (£51,017), the largest fishery on record, viz., that of 1814, which returned £105,000. In spite of the high prices, finds are reported to have been disappointing, pearl being worth not more than £9. Up to date the pearl share has netted £48,792.—*Journal of Ap.*

**Patent-office Fees.**—From a return showing a classification of the whole receipts of the Patent-office for the year 1880-81, including 100,000 five heads, viz.:—Initial stages, third year 1 year fees; other fees, certificates, sales, &c.; trade marks, the following information is given: amounts made on petitions for letters patent 100,000; on applications with complete specifications, £1 to proceed, £20,290, warrants, £18,300, 1s. £18,275, final specifications, £16,625, notices to grant, £82, notices of objection to seals of oppositions, £122, giving a total of £102,819. Fees came to £50,300, seventh year fees to £2,000, certificates, sales, &c., to £3,544; and trade marks, £4,982 and £3,784 respectively £8,766. The total receipts have, therefore, been £102,819.

**Electrical Meter.**—The want of a meter to measure the amount of electricity supplied to a consumer is often urged as one of the difficulties to be overcome before a system of electric lighting can be widely adopted. It is now stated that Mr. Edison has devised a "meter" which he proposed a year ago to fix in use with electric lamps. In the new instrument two are suspended in an electrolytic cell containing copper in solution, and placed in a branch circuit which a known fraction of the main current is sent through. Copper plates are hung upon a lever arm so as to be moved by electrolysis one has grown a certain amount (by deposition of copper) and the other grows amount lighter, the lever tips up and reverses through the cell, and at the same time moves a dial-apparatus through one tooth. The action is reversed until the tilting lever is again overbalanced, and when the current is again reversed, and another effect. Each "tip" clearly corresponds to an exact quantity of electricity through the cell, and registered indications are, therefore, proportional to consumption. "But," says *Nature*, "will it be

## OF THE SOCIETY OF ARTS.

No. 1,499. Vol. XXIX.

DAY, AUGUST 12, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## FURNITURE EXHIBITION.

Exhibition of Works of Art Applied to  
in connection with the Exhibition of  
at the Royal Albert Hall, is now open  
non-transferable season ticket will be  
member of the Society on application  
stary.

## EDINGS OF THE SOCIETY.

## PATENT LAW.

wing memorandum shows the principal  
n the law which would be made by the  
Arts' Bill for the Amendment of the  
r :—

IONERS OF PATENTS.—The Patent-office  
removed from under the charge of the  
mmissioners, who are the Lord Chan-  
Master of the Rolls, and the Law  
Three Commissioners would be appointed  
of their special knowledge.

TION FOR LETTERS PATENT.—METHOD  
NG SAME.—The method of application  
t would be somewhat as follows :—The  
would file a Provisional Specification,  
ld be referred to Examiners appointed  
pose. They would see that the invention  
subject-matter for a Patent; that the  
n fairly described the invention, and  
is generally intelligible and properly  
hey would not inquire into novelty or  
ey would report, and their report would  
o the applicant before being seen by the  
ners. The applicant would then have  
nity of conferring with the Examiners  
equired alterations. Provisional Pro-  
uld be granted immediately on receipt  
ication, and would last for nine months.  
end of that time the applicant would be  
file a Complete Specification, fully de-  
s invention. This would be referred to  
ners, and treated in the same manner as  
mal Specification. The applicant would  
to amend his Specification in accordance  
ecommodation of the Examiners, and  
ng so, a Patent would be granted. If  
ners reported that the application was

in respect of matters which could not properly be  
made the subject of a Patent, and if the applicant  
still persisted, a Patent would still be granted, but  
the objections of the Examiners would be endorsed  
upon the Specification.

DURATION OF PATENT.—The duration of Letters  
Patent would be increased to 17 years—the dura-  
tion being as now contingent upon the payment of  
fees at or before the expiration of each period.

FEES.—The fees would be half the present  
amounts, namely :—

Fee for Provisional Protection . . .	£2 10
Fee for Grant. . . . .	10 0
Fee at expiration of fourth year . . .	30 0
Fee at expiration of eighth year . . .	60 0

EXISTING SYSTEM.—Under the present law  
there is practically no examination whatever.  
Applications for Patents are referred to one  
of the two Law Officers, who reports whether  
a warrant may be issued for the granting of  
Letters Patent. The only point upon which  
the Law Officer decides is whether the invention is  
proper subject-matter for a Patent, i.e., whether it  
comes within the definition of the Statute of  
Monopolies (21 Jac. I., cap. 3) of being “a new  
manufacture within this Realm.” The Complete  
Specification, upon which the Patent is really  
granted, is never examined at all by anybody.

SUBJECT-MATTER.—The following is the defi-  
nition of “subject-matter” adopted in the Bill :—

- (a.) Any manufacture or any product not being  
a natural product;
- (b.) Any machine or any means of producing  
any manufacture product or result;
- (c.) Any process or method of producing any  
manufacture product or result;
- (d.) Any part of a machine means process or  
method of producing any manufacture product or  
result.

At present the ancient definition of the Statute of  
Monopolies is in force, but, as a matter of fact, the  
question of subject-matter depends wholly on the  
decisions of the Courts.

OPPOSITION.—Under the proposed Bill, opposi-  
tion to the granting of Letters Patent would be  
limited to persons who could state that the appli-  
cant had obtained the invention from them by  
means of fraud. Under the present law any  
person can oppose, the general ground of opposi-  
tion being that the person opposing already has a  
Patent for the same or nearly the same invention.

AMENDMENT.—The Bill provides that the in-  
ventor should be entitled to amend his Specification  
after it had been first filed. Under the present  
system this power is very restricted.

PROLONGATION.—It is proposed to continue the  
system of prolonging Patents in special cases,  
the Bill being framed in such a manner as  
to give greater facility for this than now exists.  
Under the present system, prolongations are  
granted by the Privy Council, and are considered  
a matter of special favour, whereas the effect of  
the new Bill would, it is hoped, be to give them  
as a right to any inventor who could show just  
cause for having his privilege prolonged, on the  
ground of his not having had sufficient reward, or  
the time having been insufficient to enable him to  
bring his invention into action, or similar grounds.  
The period for which a patent could be prolonged

would be diminished by the three years which the Bill would add to its original term.

**OBLIGATORY LICENSES.**—The Bill would compel a Patentee to grant licenses in cases where it could be clearly shown that the invention was not being worked in such a way as to supply the reasonable wants of the public; but the clause has been so worded as to prevent any improper interference with the rights of the Patentee over what is considered to be his own private property.

**TRIAL OF PATENT CASES.**—The Bill would provide for the trial of Patent cases in an entirely new manner. They would be tried, in the first instance, before one of the Commissioners, and an appeal would lie to the whole body. The Commissioners would have power to call in Assessors, and would have such other powers as would enable them to try the cases fully. It is hoped that this would greatly simplify the Patent litigation, and would prevent the enormous expense which is now incurred by having to bring complicated questions of law and fact before a jury, who are probably ignorant of the scientific or mechanical considerations involved. It may be noted that one great source of expense is the preparation of models, which are only necessary to illustrate mechanical questions to persons unaccustomed to deal with such questions. For experts in such matters, drawings would be sufficient; indeed, an engineer would generally much prefer proper drawings to any model of a machine.

**ANTICIPATION.**—It is proposed that a mere publication more than thirty years old, unaccompanied by use within the thirty years, should not be considered sufficient to invalidate a Patent. The object of this is to remove the hardship which now not infrequently occurs of a Patent being invalidated, or a Patentee being put to great expense in order to prove his claim, by the discovery of some ancient and probably incomplete description, a description which in many cases could not have been put into operation at the time it was made, for want of necessary appliances to carry it into effect.

**PATENTS TO FOREIGNERS.**—It is proposed that Patents should be granted to foreigners or persons resident abroad, on precisely the same terms as those on which they are granted to British subjects resident in the United Kingdom. At present Patents are granted to British subjects in respect of communications from abroad; that is to say, the theory is, a person travelling abroad sees a useful invention, brings it home, and patents it in England, such person not being, in any sense, the inventor. In practice, Patents for communications from abroad are nearly always taken out by Patent agents, whose clients are resident out of the country, and the Patent, as soon as it is taken out, is assigned to the real foreign inventor. Cases of injustice have occurred through the action of this system, in which a Patent has been granted to a person who had no moral right to it, but who anticipated the original inventor in obtaining the English Patent.

**EFFECT OF FOREIGN PATENTS ON ENGLISH PATENTS.**—At present an English Patent lapses at the expiration of any foreign Patent taken out by the same inventor for the same invention. It is proposed in the Bill that English Patents should not in any way be affected by foreign Patents.

## CANTOR LECTURES.

### THE SCIENTIFIC PRINCIPLES IN IN ELECTRIC LIGHTING.

By Professor W. Grylls Adams, F.R.S.

#### LECTURE I.—DELIVERED MONDAY, MAR

*The Production and Regulation of Electricity  
—The Laws of the Mutual Induction of  
and Magnets.*

It has been well said, that rarely do discoveries, as soon as it is made, at once furnish the results which follow as a consequence from it. Nearly all important discoveries pass through a stage of neglect or obscurity. Either the public attention is already preoccupied, or the discoveries come at a time when the public are not prepared for them, and they are regarded, and may even disappear, as authors for a time, to come forward with a fresh force in after years, when the world is in tune to receive them. Sometimes a discovery passes through a stage of quiet development in a laboratory; laws are established, apparatus is devised to prove them, attention is drawn to them, public spirit is awakened, and from a low level of the great discoverer flow new inventions, with astonishing rapidity; channels; the potential energy of the discovery is transformed into energy of action in various directions, with more or less efficiency, according to the retarding state of the medium through which the action takes place.

The progress of electrical science in various branches will afford abundant instances of several stages. If, for instance, we take the progress of telegraphy, we find that in 1816, Ronalds, in 1816, showed that electricity was practically used for conveying messages over distances; yet so little notice is taken of his discoveries by the public and by the Government, who were no longer in need (so they said) of telegraphs after the battle of Waterloo almost driven to despair, and speaks of the "leave of a science which once afforded a favourite source of amusement," and of a "cordial adieu to electricity."

It is remarkable that he should have said, "Let us have electrical offices communicating with each other throughout the kingdom," and yet the electric telegraph was not established until 20 years after (1837), only now arriving at the system of exchanges.

In a private letter, written on his 72nd birthday in 1860, he says, "If the electric telegraph of 1816 had been fairly examined, an effort might have been in the hands of the Government, and after Dr. Oersted's experiment, an improved telegraph might have been in the hands."

We shall also see other instances in connection with the special subject of my lecture, of discoveries being neglected and passed over as we say, the discoverers were men of the advance of their time, and in some cases the discoveries are again made, and are under another name. In 1815, Sir Francis Baily constructed an electric engine, which produced motion by means of Singer's electric

as 1851 this engine was still in working when it was, I believe, at the Kew observa-

813. i.e., when Ronalds was experimenting an electric telegraph at Hammersmith, by of his registering pith-ball electrometers, Humphry Davy produced the electric light between two carbons, which were joined to the two of a powerful battery.

following is a description of Sir Humphry's experiments with the electric light:—

"Mr. Pepps having had the goodness to charge the battery of the London Institution, consisting of double plates of zinc and copper, with a mixture of 68 parts of water, 108 parts of nitrous acid, and 68 parts of sulphuric acid, so as to make an arc or column of electric light, varying in length from one to three inches, according to the state of rarefaction of the sphere in which it was produced, and a powerful jet being presented to this arc or column, having it at a very acute angle to it, the arc or column is attracted or repelled with a rotatory motion, or to revolve, by placing the pole in different positions, being repelled when the negative pole was on the left hand by the north pole of the magnet, and attracted by the south pole."

In a few cells of some of the more powerful batteries, such as Grove's, or Bunsen's, or the Daniell's, or the potash battery we may readily reproduce the celebrated experiment of Sir Humphry

and Davy discovered the electric light in 1801. At that time little was known of voltaic electricity, and that the current decomposed salts, and was accompanied by chemical action in the electrolysis. Davy had obtained the metals potassium, sodium, barium, strontium, calcium, and magnesium by the electric current. The relation between electricity and magnetism was still unknown.

In the year 1820, Oersted first observed the action of the current of electricity on the magnetic needles, and thus gave a very ready method of comparing the effects of different currents, by balancing these on the needles against the effect of the earth's horizontal magnetic force. In the same year Ampère discovered the law of the action of the current on the magnetic needles, and produced his celebrated theory of magnets and of terrestrial magnetism. According to this theory, a particle of a piece of steel which forms the core of a solenoid has currents of electricity circulating round it in the same direction, and the magnetism of the solenoid is only the resultant action of all these currents taken through the whole of the piece of steel.

Thus magnetism is the resultant action of the currents.

Ampère's experiments (which were repeated in the lecture) showed the mutual attraction and repulsion of parallel currents, and of these and magnets; also that a current in a straight wire or in a flat coil, acts as a magnet; and that a hollow coil carrying a current attracts a piece of soft iron and holds it up.

These elementary experiments are now very common, and they may be very well known; but, as we shall see in the lectures which are to follow, these early and simple devices are found to be among the most efficient for controlling and directing the current and steadying the light in

some of the best electric lamps. Whilst Ampère was developing Oersted's experiment in one direction, Schweigger in the same year (1820) employed it for the comparison of currents, and invented the galvanometer. Then followed improved galvanometers by Becquerel and others; and in 1827, Ohm gave his simple theory of the action of batteries which was deduced from Volta's principle, and this has formed the groundwork of all later investigations of the subject.

If we consider these simple experiments of Oersted and Ampère in their relation to the now well-established principles of conservation of energy, we may arrive at some important conclusions which again are fully borne out by experiment. Thus, when a current of electricity passes along a wire in Oersted's experiment, part of its energy is spent in overcoming the resistance of the wire, and another part is spent in causing the motion of the magnetic needle, i.e., in doing work upon it in opposition to the pull of the magnetic force of the earth upon it. This part of the energy, which is spent in twisting the magnetic needle about the axis, leaves less energy to be spent in producing the current, and so there is less current passing in the wire when the magnet is in the act of being deflected than there is in the same wire when there is no magnet. When the magnet is held at rest, or when it has settled into its position of rest, there is no longer any energy spent in keeping it there, and the full current again passes in the wire. Thus a current which deflects a magnet, is itself diminished by that motion of the magnet. Take again any of the simple experiments of Ampère on the mutual action of currents of electricity upon one another, and the motion of conductors carrying those currents. There is a conversion of energy of the current into motion of the conductor carrying the current in parallel wires attracting one another, and hence there is less current in the wire while the motion is actually taking place. Thus the approach of two wires carrying currents of electricity diminishes the currents flowing in the wires.

Now if the approach of these wires diminishes the currents in them, then the separation of the wires may be expected to increase the currents flowing in them, for in the separation work is done in the opposite direction. Hence, in the alternate approach and separation of the wires as they oscillate, the currents are diminished and increased alternately. If there be no current at all in one of the wires, then the separation of the two wires will give a current in the one which had no current in it, and the approach of the wires will give a current in the opposite direction. Thus we are led, by the well-known principles of energy, to results which are well-known to be true by experiment, that the separation of the parallel wires, one of which is carrying a current of electricity, produces in the other wire a current of electricity in the same direction or a direct current, and their approach produces a current of electricity in the opposite direction, or an inverse current.

Let us pursue this relation of the principles of energy to the effects produced by electric currents a little further. With two parallel currents in two approaching wires, the amount of energy used up, and therefore producing no effect in the shape of current, depends on the amount required or ex-

the velocity of falling, so, in the case of currents of electricity in wires approaching one another, the energy expended is measured by the square of the velocity of approach; so that the alteration in the current takes place more and more rapidly as the rate of approach is increased. If, again, we apply this to the case where one of the wires has a current in it, and a second parallel wire has no current in it as long as it remains at rest, then the amount or strength of the direct current in the second wire will increase at a more and more rapid rate as the velocity of separation of the wires is increased, and the strength of the inverse current in the second wire will increase at a more and more rapid rate as the velocity of approach of the wires is increased.

Here, then, we have the laws of the production of induced currents deduced according to the principles of energy from the relative motion of parallel currents, discovered by Ampère. These laws are of such importance in connection with the subject of these lectures, that I shall illustrate them a little farther by a few simple experiments, showing the effect of rate of approach or separation on the induction current.

Instead of actually removing the coils, if the current in the primary circuit be diminished, the effect is the same as if a wire carrying a part of it had been taken away, and so there is a direct current induced in the secondary wire, whereas, if the current in the primary wire be increased, the effect is the same as if a wire carrying the additional current had approached, and so an inverse current is induced in the secondary wire.

We shall get the greatest rate of separation by suddenly stopping the current in or breaking the primary current, and the greatest rate of approach by suddenly joining or making the current flow in the primary circuit. Hence, breaking the primary circuit produces a very intense rush of electricity, giving a direct current of great intensity in the secondary wire; and making the primary circuit gives a powerful inverse current in the secondary

in A, there was no current induced in B; making contact in A, or on approaching it, there was a momentary inverse current induced in B on breaking contact in A, or on separating the wires, there was direct induced current in B, as this current was of the nature of a wave, like the shock of a Leyden jar, magnetise a steel needle, although it had only a slight effect on a galvanometer, and the expectation was confirmed, and that there was magnetised opposite ways on making and breaking contact.

Then, in his evolution of electricity from magnetism, he gives an account of the increased effects on introducing soft iron into his helices of wire, and shows that similar effects were obtained by using ordinary magnets instead of a helix carrying a battery current, and an iron core, i.e., in place of an electromagnet. Also, in place of a cylinder of iron in the helix of wire, he uses a welded soft iron cylinder, 1-1/2 inches in diameter, and 7-8ths of an inch in thickness, with helices wound round it, what would now be called a Gramme machine. He remarks that the iron cylinder arrangement was not so powerful as the ring arrangement, and that the core within the helix, he magnetised by bringing permanent magnets in contact with its ends, and observes "a deflection which was due to an induced current of electricity in the cylinder in the direction to that fitted to form a magnet of the same polarity as that really produced by the contact with the bar magnets." Such a current would have converted the cylinder into a magnet of the opposite kind to that formed by the poles A and B, and such a current would flow in the opposite direction to the current in the helix. In, Ampère's beautiful theory, are contained the principles constituting a magnet in the position figure, bringing the bar in contact with the poles of the magnet, a current is induced in the wire in the direction indicated in the figure.

He then describes the experiment of inducing a current in a wire by the motion of a magnet.

the rate of separation of the coils of the loadstone, he concludes:—"An agent which is conducted wires in the manner described, so passing, possesses the peculiarities and force of a current of which can agitate and convulse the and which finally can produce a be electricity."

the discoveries of Faraday, made in the year 1831, we shall find to be of importance in magneto-electric machines, and the time between induction by a current in a coil and induction by a current requires a considerable interval of time to its full strength. Faraday explains this retardation by supposing that the induction of the Ampèrian currents is retarded, so that the magnet requires time to develop its full power.

Consider for a while the work of the last fifty years ago, in his first series of experiments the Royal Society, could establish so magnetic and current induction, and the rapid development which has taken place in the science of electricity, and the production of magneto- and electric machines.

## ISCELLANEOUS.

### THE AMERICAN SCIENCE AND MECHANISM.

#### COMPOSITION OF COMETS' TAILS.

If spectroscopy is known to have made in the United States, and a few of its results justly considered to be entitled to be subject with authority. Professor College, has, among others, bestowed upon the comet, and has just published its results, and the deductions he makes therefrom that the light emitted by the tail of a comet is, rather strongly, in a plane perpendicular to the sun's place. Not only has he fixed the polarisation, he has also measured its intensity. His experiments he infers that a large amount of light of a comet's tail is reflected sunlight, amount being greater than if the tail were composed of solid masses, in that matter of the tail is in the form of gas or vapour. Microscopic examination proves that the tail is partly by its own light, and partly by that of the sun. The origin and nature of the light which forms the tail may be inferred from the results of recent discoveries concerning the composition of comets and meteorites. Formerly it was held by Professor Wright indicate that in large quantities of gas, with a combination of water, and that at a temperature of red heat, gas is given off at a rate of over two inches for every cubic inch of substance, beside the water vapour. The gas is composed of hydrogen, carbon dioxide, and carbon, the latter in the greater proportion, and also of ammonia and nitrogen. Inclosed in a glass tube at low pressure, and made luminous by electric discharge, the meteoric gases give a blue light, under suitable conditions, is seen as the usual cometary spectrum of bright

### THE AMERICAN RAILROAD-CAR VERSUS THE COMPARTMENT CARRIAGES.

The alleged advantages of the American railroad-car over the close compartment system preferred in England is being much discussed here, in consequence of an assassination which lately took place in one of the latter. It may possibly be claimed by those favouring the compartment system, that with such a construction of carriages no such outrage could possibly have taken place as that which is, at this moment, the leading theme in American newspapers. In a part of the country which, Dr. Russell will be telling you, abounds in lawlessness, a railway train left a station, Winston, on the Rock Island and Pacific Railroad, about nine o'clock at night on the 15th inst., when it was boarded at every point by a band of twelve well armed and thoroughly experienced desperadoes. Two jumped on the locomotive, and drove off the engineer and fireman at the revolver's muzzle. Others by similar means prevented the interference of the passengers with their schemes, while the remainder devoted their attention to the safe in which valuable property was contained. There was also some bullion in the form of bricks of silver. Several shots were fired at non-complying or resisting officials, the conductor being killed. No attempt was made to rob the passengers. Now, when the character of the attacking party is considered, it will be seen that such an outrage might have been made not only on a train of compartment carriages, but on one going over even the North London or Metropolitan Railways. The band is composed of old experienced hands, well-known in connection with innumerable deeds of daring, possessed of desperate courage; they have a perfect acquaintance with all the western country between Iowa and the Indian Territory. Their operations are conducted on a large scale, and are almost invariably successful. Their leader is one or the other of the two James brothers, whose mother, now Mrs. Dr. Samuels, is credited with the planning of the outrages so boldly carried into practice by the gang, who must not be compared with the sneaking banditti in Sicily or Greece, as will be seen by the following few examples out of numerous others of a like nature. In 1868, desirous to give a "benefit" to a sick member who wished to go to the seaside, a party of about a dozen, well mounted, dashed into the town of Russellville, Kentucky, during business hours, drew up in front of the bank, and "covered" with their revolvers the townsmen who were passing while two went in and robbed the bank. The following year a similar feat was accomplished in Galanta, Mobile, on which occasion they shot the cashier. Two years afterwards, in 1871, this was repeated, including the shooting of the cashier, in Columbus, Kentucky; and in 1872 a party of six of the gang did the same in Corydon, Iowa. In the same year, and while there were 20,000 people present at the Kansas City Exhibition, they made a successful raid on the cashier's office. They have robbed many banks and the express cars of several trains, and on at least one occasion of the latter nature they impudently sent a telegraphic despatch to the St. Louis newspapers reporting the occurrence before they rode away. Several members have been shot down during hot chases and conflicts with the inhabitants, but no one, even when dying, has ever yet told who his companions were. The recruits are selected from the guerillas of the Southern Confederacy. Many stories are told of their exploits, and these stories, although wonderful, are said to fall short of the reality. Among those who have been shot by them are six detective officers, three of whom belonged to Pinkerton's Detective Agency, New York. Why I have entered at such length on the *personnel* of the gang is this—In the Society of Arts sooner or later the subject of the assimilation of English railway carriages with those of America will be brought forward, and it is more than likely that those unfavourable to the American system will cite the recent robbery as

costs in New York two and a quarter dollars (about nine shillings and fourpence halfpenny) per thousand feet. At present there is no indication that the electric light will be supplied at quite so cheap a rate, although orders are pouring in faster than they can be filled. Now, while many are guided by the novelty and beauty of the new light, and are willing to pay a little more for it, the great majority of the public will be guided by considerations of cost, and will not be readily tempted to incur the expense of fittings for the electric light. By keeping the price of gas so greatly in excess of what the companies admit that it can be sold, these companies are allowing the electric light to obtain a footing from which it may not eventually be easy to dislodge it, more especially if by recent and forthcoming inventions connected with the storage of electricity the prices be reduced, an idea apparently ignored by the gas companies. The more probable theory is that, believing in the ultimate practicability of the electric light, the gas companies will adhere to their present high prices until the electric opposition makes itself too strongly felt, when, all at once, the price to consumers will be reduced to such an extent as will cause the rival bodies to stagger. That this can be done is apparent from the fact that coal is dearer in London than in many places in this neighbourhood; for example, in Philadelphia, where coal is 4s. 2d. cheaper per ton than in London, but where gas costs three times as much as in London. This high price, in the large American cities, arises from there being no competition in the making and supplying of gas as there is in other necessities or luxuries of life. That a good dividend could be paid at 75 cents. (3s.) per thousand feet is not denied, and the great hope of the public now is, that by improvements in electric lighting, gas may come to be reduced to this price.

#### NEW METHOD OF STORING ELECTRICITY.

An Ohio electrician, Mr. Charles Brush, of Cleveland, having for several years been engaged in devising means for storing electricity, has now had his labours crowned with success, the means by which he effects this being different from that of M. Faure, which is based on the invention of Planté, several years prior. Brush may or may not have obtained results equal to Faure some years ago, as he claims to have done; what

the new "Industrial Encyclopedia" (Spon), is considerable attention among Continental agriculturists and has recently been experimented on with its value as a food for milch cows and fat cat

The beans were first given alone, to test. The cattle took them very readily, but the quantity of saliva was required in their mastication and it was found better to mix them with food.

First, as to the results with milch cows. divided into two parties. During the first experiment, when the cows received no food but they gained 1.15 lbs. in weight, and gave of 10½ pints of milk each per diem. During the second stage, when the first portion of beans was given, half the cows, their weight increased by 1.2 lbs. milk by .17 pint, and the cream by 1½ per cent. The other half of the cows, which received grain of beans, grew 1.93 lbs. in weight, and fell off of milk each per diem, with no difference in percentage of cream. In the third stage, the cows which had beans in the second stage were given grain, with the result that their weight increased .72 lb., and the milk yield fell off 1 pint per diem, while the cream increased ½ per cent. The other half of the cows, which had had grain in the second stage, increased 1 lb. in weight, milk yield fell off .61 pint each per diem, as increased by 1½ per cent. In the fourth stage, the cows which had grain again reversed. The cows which had grain, on receiving beans, increased .59 lb. 2.34 pints in milk yield, and 2½ per cent. in cream; while those which returned to grain fell off .86 lb. in weight, and 1.86 pints in milk yield, though the cream increased 1½ per cent.

The fattening cattle were also divided into two parties. During the first stage without fattening, the cows increased in weight 72.73 lbs., being .64 lb. each per diem; the other only 11 lb. each per diem. The difference was owing to exchanges of food. In the second stage, the lot which had had beans increased 22 lbs., or 19 lb. each per diem; those which had grain instead increased 158.68 lbs., or 1.41 lb. each per diem. During the third stage, the lot which had beans grew 185 lbs., or 1.65 lb. each per diem; the other lot fell off 39.67 lbs., or .35 lb. each per diem.

is, therefore, the soy bean is superior to fat cattle, it is less adapted, and ranks lower.

It can be cultivated in Central and Eastern of similar localities, especially in unfavourable when other crops are backward. For a field crop, it is recommended to be sown in April in the middle of May.

Litter of the beans grows in diluvial and is shown by the following analyses:—

	Diluvial.	Alluvial.
.....	15.20	15.60
.....	16.21	17.04
.....	28.03	25.04
gumous extractive matter..	30.04	33.16
.....	4.38	4.46
water .....	4.74	8.82

Stem or husks of the plant is practically worthless for cattle, but the husks and leaves, mixed with food, or even alone, are readily eaten. It was found that the chopped beans, soaked for a water containing a little salt, are greedily eaten, and that few pass through undigested.

#### EXPLOSIVE POWERS OF DUST.

It has been presented on the results of experiments with samples of dust collected at Seaham in compliance with the request of the Home Department:—"The results of the experiments at Seaham and other dusts appear (says Mr. Dave demonstrated—(a) That coal-dust in only much promotes and extends explosions by reason of the rapid inflammability of the dust combustible, and of the readiness with which it comes and remains suspended in air-currents, &c. it may also be itself readily brought into as a fiercely burning agent which will carry off as far as its mixture with air extends, operate even as an exploding agent, through a small proportion of fire-damp in the air of the existence of which, in the absence of the dust, would not be attended by any danger. (b) That coal-mines, quite apart from any inflammability it may possess, can operate in a distinct manner as a finely-divided solid, in determining the effect of mixtures of only small proportions of fire-damp, and consequently in developing explosive (c) That a particular dust in a mine may, under certain circumstances, be a source of danger, even though it contains a small proportion of coal or combustible.

Although the explosion which may occur by agency even of a non-combustible powder, under described, may be of very mild or feeble in the first instance, it may be almost at once of great magnitude and violence by coal-dust, which ignition will raise and bring into action. The operation of fire-damp required to bring dust in a mine into operation as a rapidly burning or an exploding agent upon a small scale, and with the application of a small source of heat or flame, is below the amount which can be detected in the air of a mine by the most experienced observer, with the present in use, as has already been demonstrated by the experiments of Mr. Galloway. Indeed, a dust of highly sensitive or dangerous character, under certain conditions, and very possibly with dusts less than the least sensitive of the Seaham dust, in the presence of a source of considerable heat, such as blown-out shot or an overcharged hole, will, under a small proportion of fire-damp, the presence of which in the mine might not be in the least suspected, may serve as the inciting cause to the outburst of an explosion of coal-dust. In the

complete absence of fire-damp, coal-dust exhibits some tendency to become inflamed pending a very large lamp flame at a high velocity; if exposed to the action of a large volume of flame, such as produced by the explosion of freely exposed gunpowder or gun-cotton, it exhibits, in addition, a decided tendency to carry or propagate flame. But, so far as can be determined by experiments on a moderate scale, this tendency is of limited nature, and very different indeed from the property of carrying or propagating flame, which even comparatively non-sensitive dusts possess in the presence of a very small quantity of fire-damp. In conclusion, it may be admitted as possible that, with the large volume of flame and the great disturbing effect of a blow-out shot as the initiatory cause of the ignition of dust, and its suspension in the surrounding air, such inflammation may, in the complete absence of fire-damp, be propagated to a greater distance than the results of small experiments would warrant one in assuming. But it can scarcely be maintained that the air of a mine in which the coal gives off gas at all can be at any time free from fire-damp; and as the existence of very small and unsuspected quantities of that gas in the air of a mine may suffice to bring about the ready propagation of flame by coal-dust, and thus to develop violent explosive effects, it would appear needless to assume that coal-dust may, in the entire absence of fire-damp, give rise to explosions, even of only limited character in coal mines, in order to account for casualties which cannot be ascribed to the existence of accumulations or sudden outbursts of fire-damp."

#### THE SALT CAVES AND MINES IN THE PERSIAN GULF.

From a recent report by Assistant-Surgeon Abder Rahem, it appears that in that part of the Persian Gulf lying between latitude 26° 16' and 27° 10' N. and longitude 53° 50' and 56° 30' E., is an extensive area, abounding in a large deposit of salt, which crops out at various places on the earth's surface, rising up into ranges of rocks of no little magnitude. The following are the principal places from which salt is obtained in this area:—Kowin, on Kishm Island, Hormus, Larak, Pahal, near Khamir, Sir-bu-Nafair, Jabal Bostana, and Hamaran, on the Persian coast. The salt-bearing rocks are of a reddish colour, from red ochre, varying from earthy consistence to stony hardness, which covers the salt deposit, and is more or less mixed with it, imparting to it a red tint. The ochre is associated, to a small extent, with specular iron ore. The association of the ochre with salt is so constant in the salt area that the existence of the former is almost a sure indication of the presence of the latter. About 16 miles from the Basidore Station in a south-easterly direction, and three miles from the village of Kowin, on the island of Kishm, is a range of rocks bordering on the sea, and consisting (very largely) of rock salt covered in some parts by red ochre, while in others large masses of salt of stony hardness and reddish tint compose the surface and mass of this rock, giving it the appearance of a structure made of red bricks and mortar. A salt cave is situated in the western end of the range of rocks, and besides this there are several other places where briny water issues, and collecting in hollow ground close to these rocks, deposits beautiful crystalline masses of salt by spontaneous evaporation. It is stated that some forty years ago, the salt was largely procured by this method; numerous shallow pits were excavated, where, as the brine evaporated, it deposited salt, which was then collected for commercial purposes, but since the natives commenced to quarry the salt, the pits were neglected, as the process was tedious, and the salt obtained, little in quantity, and not good in quality for commercial purposes; at the present time, however, the streams of brine and some of the pits still exist, and

The mines which yield the present salt are situated about two miles from the seashore, and the path leading to them winding between the rocks is very difficult for the camels to traverse. The salt is brought on the beach by the camels, costing about 4s. for every "bahar," or ton and a-half, and calculating the customs charges at 1s. 6d., and the cost of quarrying at 5s., the total cost of the salt on the beach would be about 10s. 6d. per ton and a-half. Recently salt of an excellent quality was quarried from the rocks, about 100 yards only from the seashore, thus saving the cost of carriage to the miners. The salt mines at Hameran are also extensive. They are situated about four miles from the seashore, and the salt is found in beds of about 4 ft. thick, with intervening layers of earthy material. The salt beds are hard in consistence, and are broken by means of gunpowder, the masses being subsequently reduced to granules by wooden and iron mallets. Some of the specimens found were of a pale greenish colour, from an earth of that tint. This earth exists in isolated deposits and mounds, varying from earthy softness to stony hardness, the green tint being produced by the influence of manganese. The quarrying expenses at these mines are about 5s. each ton and a-half, camel hire amounting to about 4s. 6d., and boat hire to Lingah being about 3s. Large quantities of salt are exported by native boats to Muscat, whence it is carried by merchant vessels to Bengal, Zanzibar, Mauritius, Batavia, &c. There is an average annual export of from 25,000 to 30,000 tons of salt from these mines, the best quality coming from the Kishm Island and Sir-bu-Nufair. The price of salt at Lingah varies from 4 to 5 dollars, while at Muscat it is from 5 to 6 dollars per "bahar," or ton and a-half. There are, in addition to these caves and mines, certain springs in the rocks close to the village of Salakh, near Henjam, the waters of which are warm, and charged with salt, yielding naphtha of a reddish colour. It is highly combustible, burning with thick smoke. The natives use it for purposes of light, and also use it locally for rheumatic complaints.

#### JAPANESE LACQUER AND PAPER.

The manufactures of lacquer and paper, two industries for which the Japanese are deservedly celebrated, were made special objects of study by Sir E. J. Reed

fire. This side of the paper is then applied to lacquer to be decorated, and the paper is then pressed upon it by means of a small spatula. The transfer of the pattern from the paper to the lacquered surface is further assisted by beating the paper down with a small stone containing powdered stone. The paper is then peeled off, and can be used again if desired. A slight relief of the pattern so produced by lacquer is rubbed down with carbon polish, and that alone, is then lightly covered with a thin layer of quickly-drying varnish. Gold is then applied to the moist surface by a camel-hair pencil if the gold powder be fine, or by means of a small tube if it be comparatively coarse and heavy. The article is then dried for warm clothes, such as is used for drying of lacquer varnish. The design is next lightened with a very thin layer of varnish, applied with a paper steeped in it, and passed very lightly over the object, which is then redried. The object receives further extremely light layers of varnish, and subsequent polishings before being plated. Silver is applied in powder in the same manner. When gold or silver is applied to designs in details of the process vary considerably. The application of the metals is effected in the same manner. When gold and silver are laid upon the varnished surface for them, and dealt with in the usual manner, varnish acting as a "size" for the metallic mother-of-pearl is used as an incrustation. It is laid on during the varnishing process, and it is thicker than if it be thin, and the final process is continued until the pearl is brought to

#### PAPER.

Besides the papers made from rags and by European methods, the true Japanese paper is produced from a limited number of materials, the kinds being *Hishi*, from the *gampi* (*Wickströmi*) and allied plants, and *Kobushi*, from *Kodzu*, or paper-mulberry (*Broussonetia*), which latter is the more important. The *Kodzu* plants for paper-making purposes are cut into 3-foot lengths, and steamed in a boiler containing a little boiling water. The

gummy decoction from the bark of the *neri-neki* (*Hydnocarpus pinnatifida*), or from the root of the *terere* (*Torreya bitorata*). When the steeping in this mixture has proceeded sufficiently long, the pulp is spread out into sheets by means of fine sieves of bamboo and silk. After draining, the sheets are transferred by means of rollers to drying-boards.

Similar processes are employed for producing paper from the *gampi*. The product is very fine and supple, and admirably suited for taking transfer copies, besides possessing the advantage of not becoming worm-eaten. It is also made from the *mitu-mala* (*Edgeworthia maculata*).

#### CEYLON PEARL FISHERY.

The pearl fishery which has just closed in Ceylon has been one of the most successful on record. The pearls procured from the oysters on the banks situated off Malakur, on the western coast of that island have been famous from time immemorial for their purity, shape, and colour. In these attributes they far surpass those obtained from the oysters of the Persian Gulf, although they are, as a rule, inferior to the latter in size. The oyster of the Arippe banks is scientifically known as the *Melagrina margaritifera*, and is of a species not existing on all pearl oyster banks, and of a different genus altogether to that found in the Tambraparni Lake, near Trincomalee, on the eastern coast of the island, which is termed the *Placuna placenta*. The earliest fishery of which we can find any detailed record took place in the year 1796; and from that date the Ceylon Government, up to the year 1874, derived a revenue of £1,013,113 from this source. The pearl oyster is notoriously migratory in its habits; and from one season or another the banks are for years together almost totally deserted by them, and long intervals elapsed during which the fishery has from this peculiarity been closed, rendering the return from it quite unreliable as a source of settled revenue. Thus from 1732 to 1746, from 1768 to 1796, and from 1833 to 1854, there were no fisheries at all, and it was feared that the latter date that the oysters had altogether deserted the banks.

A few words descriptive of the system under which the fishery is conducted will be of interest. A report having been received from the inspector that there were sufficient oysters of mature age on the banks, the Government advertises a date for its commencement. A large number of boat-owners, both Ceylonese, and from the opposite coast of India, apply to enrol their boats, and these, probably to the number of 150 to 180, are divided into two fleets, sailing under red and blue flags, which proceed to the banks, situated some six miles from the shore, on alternate days. Each boat provides its own crew and divers, and has on board a guard, whose duty it is to see that the oysters fished are not surreptitiously disposed of. Each diver stands on a flat stone attached to the diving rope, and after taking a long inspiration, closes the nostrils with one hand, and descends on the stone to the bottom, where he hastily collects as many oysters in his basket as the time he is able to remain at the bottom admits of. This varies very much with the capacity of different men; but, in spite of all assertions to the contrary, we believe that few divers can stay below beyond 45 seconds. At a given signal the boats all sail for the shore, and on their arrival they are unloaded under inspection, and the oysters placed in the Government kottos—palisaded enclosures with a cement floor. Here the oysters are counted, and the proportion due to the boat-owners for their services is made over to them. The remainder, which is the property of the Government, is put up to auction and sold to the highest bidder. The purchasers remove their lots to private kottos, where the oysters undergo the disagreeable process of rotting, to enable the pearls to be washed out. The stench resulting from

this decay is fearful, and it has often happened that the operations have had to be prematurely closed in consequence of the resulting outbreak of cholera. It says much for the careful sanitary arrangements made by the officials in charge that such outbreaks are not of recent occurrence.

The official estimate of the proceeds to be expected from this year's fishing was 400,000rs.; but this estimate has been considerably exceeded, the returns having been 599,333rs. To some considerable extent this increase is due to the improved demand in India for pearls, the competition having been very keen. As yet, official returns have not been published; but the *Ceylon Observer* has kept its readers very fully informed of the results of each day's fishing, and of the prices obtained. The total number of days on which the weather and other conditions allowed of operations being conducted was forty, and the fishing finally closed on April 27. The number of oysters fished during that period is reported to have been about 17,000,000, and the average price realised for them about 34rs. per thousand, though they occasionally brought as high prices as 43rs. per thousand.—*Ceylon and India*.

#### CORRESPONDENCE.

##### A NEW THEORY CONCERNING BOILER EXPLOSIONS.

Referring to the last paragraph, p. 727, in the *Journal* of the 6th inst., on "A New Theory concerning Boiler Explosions," it is just 40 years since I saw the new high-pressure steamer *Telegraph* leave the Custom House, at Greenock, with a large party on board, for Helenaburgh, on the opposite side of the Clyde. Watching her anxiously with a glass, I noticed that she arrived safely at the small quay or landing-place then existing there, but immediately after she was literally blown to pieces by the bursting of the boiler, which was hurled completely over the quay. Many persons were killed, and many more seriously injured.

I mention the occurrence as it may enable any of my brother members who may desire full details to obtain them.

JOHN WM. WOOD,  
Collector of Customs.

H.M. Customs, Harwich, Essex.  
August 8th, 1881.

##### TURKISH OFFICIAL STATISTICS.

Two interesting and noteworthy subjects appear in the *Saatinami*, or Official Almanack in Turkish, of 1296 (1881), a Year Book published at the Ministry of Public Instruction. The one is a statistical account of the exports and imports in Turkey proper for the year 1294 (1878), and the other is a census of the male population of the Empire, as well as the enumeration of dwellings in each Vilayet. The value of the former is particularly enhanced in consequence of the detailed statement of the commercial movement which took place with each country separately with which Turkey stands in commercial relations, and because it is the first work of the kind published by the Government. It will be observed that England figures in these accounts for over  $\frac{1}{11}$  of the entire amount.

Bearing in mind too that the general commercial movement, as shown in the following table, cannot be taken as a normal standard of the commerce of this country, 1878 was the year when the Turco-Russian war was terminated; a great part of the Moslem male population were kept under arms for two consecutive years, which deprived agriculture of its hands; while some of the richest provinces of the Empire were devastated by the war, locusts, and famine, this must have caused a diminution in the

general exchange of at least one-third. The second part, viz., the census of the population, although incomplete, is yet interesting in so far as it gives an approximate idea what the population of Turkey proper is, or, at all events, what the *Sasinski* assumes it to be.

Without entering into the accuracy of the following items, I will merely confine myself to reproduce the statements of the *Sasinski*.

TABLE I.—STATEMENT OF IMPORTS AND EXPORTS FOR THE YEAR 1294 (1878).

Imports.

Assuming the male population of Constantinople to be 350,000, and allowing for the incomplete or certain Vilayets, as well as Bagdad, Tripoli in B &c., the entire population of Turkey proper is likely amount in round numbers to *exceed* including the female sex.

S. STAB,  
Cor. Memb. Society  
Constantinople and Smyrna, 27th May, 1881.

GENERAL NOTES.

**Commercial Geography.**—A letter has appeared in the *Times* from Mr. E. J. Wetherston stating the establishment in this country of institutions similar to those working in Germany, under the "Societies of, or for, Commercial Geography"—"für Handelsgeographie." The objects of these are—first, to give their members information regard channels into which the export trade of the country be directed; secondly, to establish agencies in principal commercial towns in the world. This is the model of Lloyd's. In like manner as Lloyd's report concerning ships, shipwrecks, and all matters to navigation, to the head quarters in London, so the agents send in reports upon all matters relating to the commercial requirements of their districts to the "Central für Handelsgeographie" in Berlin, which reports are published in full in the "Geographische Nachrichten," non-members for the sum of two marks, or 2s. The agents includes some of the most eminent Germans abroad, men of scientific renown, anxious for their own welfare.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,500. Vol. XXIX.

FRIDAY, AUGUST 19, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.O.*

## NOTICES.

## ART FURNITURE EXHIBITION.

Exhibition of Works of Art Applied to  
e, in connection with the Exhibition of  
s at the Royal Albert Hall, is now open  
A non-transferable season ticket will be  
ny member of the Society on application  
cretary.

## MEETINGS OF THE SOCIETY.

## CANTOR LECTURES.

SCIENTIFIC PRINCIPLES INVOLVED  
IN ELECTRIC LIGHTING.

Professor W. Grylls Adams, F.R.S.

RE II.—DELIVERED MARCH 14, 1881.

*Measurement of electric currents.—Efficiency of  
o- and dynamo-electric machines.—Heating  
of the current.*

the discovery of the principles which I  
d in the last lecture, and the method of  
g currents of electricity by the inductive  
magnets, or currents in motion, the laws  
currents were being developed; but, for  
ears after Faraday's discovery in 1831 that  
en removal of a coil of wire from the pole  
net gave rise to a current, nothing was done  
these laws for the purposes of electric

Voltaic batteries were being improved,  
more constant and more powerful batteries  
all, and Grove, and Bunsen were dis-  
and these were the sources employed to  
the more powerful currents of electricity.  
country Grove's battery was the favourite;  
in laboratories we may say that, up to the  
time, the 40 or 50 cells of Grove have  
een used to give us the electric light.

used for optical experiments in the labora-  
source of light should be as steady as  
and as the carbons burn away, their  
would be continually brought to the same  
; hence the elaborate arrangements of  
ark and electro-magnets devised by Staité,  
and by Foucault, which have reached  
at perfection in the hands of Duboscq.

One of the carbons, that connected with the  
positive pole of the battery, burns away twice as  
fast as the other, and hence the wheel-work must  
be adapted for feeding these carbons automati-  
cally at the proper rate.

When the current flows always in the same  
direction in the arc, as in this case where Grove's  
battery is used, and in all cases where the magneto-  
machine is adapted for producing continuous cur-  
rents, the positive charcoal point or carbon be-  
comes hollow, and wears away more rapidly; and  
the negative carbon becomes pointed, and wears  
away about half as fast.

In the Duboscq lamp, the positions of the points  
of the carbon are kept as nearly as possible the  
same; the carbons are moved towards one another  
by means of a drum carrying two wheels, whose  
diameters are as two to one, which move  
two racks, which carry the carbons towards  
one another. This lamp is far too compli-  
cated and delicate in its mechanism to use with  
magneto-electric machines, and therefore the  
system adopted in it, for regulating the current  
and regulating the carbons, requires considerable  
modification, before this lamp can be adapted for  
general use for the purposes of electric lighting.  
It is especially adapted for use with optical  
apparatus, and for showing by projection on the  
screen the special characteristics of the arc formed  
by the glowing gases of various substances. We  
may use it now for showing the character of the  
arc formed by silver converted into a glowing gas  
by the intense heat of the arc. This arc shows us  
that silver is rich in the violet or chemical rays,  
and points to the reason why the salts of silver are  
of so much use in photography.

## ELECTRIC REGULATORS OR GOVERNORS.

By the laws of Ohm we get the relation  
between the electro-motive force, the current, and  
the resistance expressed by the statement—

The product of the current by the resistance in  
a circuit is equal to the electromotive force in  
that circuit, or  $E = C(R + r)$ .

Regulators may act so as to control—

1. The electromotive force and internal resis-  
tance of the battery or dynamo-electric machine.

2. Or they may control the useful resistance in  
the circuit.

3. Or they may control the external resistance,  
which does not produce useful work.

Regulators which control the current by alter-  
ing the electro-motive force or internal resistance  
of the source of electricity, so as to counterbalance  
other distributing effects, are not practically of  
much importance, and so need not detain us long.  
Suppose, for instance, that an increase of current  
acted on a rotating governor in such a way as to  
raise the plates out of the battery, thereby increas-  
ing the internal resistance, this would diminish the  
currents which would so re-act on the governor,  
and again lower the plates. Or suppose the  
current passes round a coil which is set with its  
axis vertical, and that an iron rod supports the  
carbon and zinc in a bichromate of potash battery,  
and passes into the axis of the coil, then, as the  
current increases, the coil draws up the iron core  
and the battery plates, and increases the internal  
resistance, which diminishes the current.

Regulators which act on the useful resistance in

diminishes the efficiency of the machine in order to maintain a steady current.

There are many ways of varying the external resistance of a circuit; for instance, a rheostat set in action by clockwork, which is started by an armature of an electro-magnet placed in the circuit. If, for instance, as the current is weakened, the armature of the electro-magnet falls and releases a wheel of a clockwork arrangement, which diminishes the resistance by unwinding the wire of the rheostat. The methods which have been employed have been gradually simplified, and it is found that the simplest means are at the same time the most efficient. For weak currents, Edison's system, whereby a greater or less pressure on powdered carbon increases or diminishes its conductivity, has been employed. Edison also devised a regulator or shunt for the current, by the expanding of a platinum spiral wire placed in the lamp which short-circuited the current on reaching a certain definite temperature. Suppose, for instance, that an arrangement is made by which, when a current increases, part of it is sent through an electro-magnet, which draws up an arm so as to break the direct circuit, and send all the current through the electro-magnet, the resistance of the coil of the electro-magnet reduces the current, the arm falls, and again the current passes through the direct circuit.

#### LANE-FOX REGULATOR.

The regulator is an electro-magnet of very high resistance, which takes a branch of the current and acts on one end of a lever. The other end of the lever makes contact with one or other of two pins, which are connected with one or other of two coils forming electro-magnets, called respectively H and K, which govern either the throttle valve of the steam engine, or which may be made to introduce extra resistance by sliding contact over the wires of a rheostat. When the lever touches one of the pins, a current passes through the lever to the electro-magnet H and turns the arm in one direction and

necessary to bring the deflections to about a shunt of very small resistance, which is a very small part of the current through the galvanometer. Here there is a liability in the measurement of the resistance of the galvanometer. The objection to this method is, that the quantity is measured by the galvanometer, the error of the observation is multiplied by a thousandfold, or even very much more, in order to arrive at any idea at all of the current flowing in the principal circuit. The only method to attempt is to compare the flight of starlings, or of a covey, or measuring or marking, as accurately as possible, the flight of one particular bird which separated from the rest, and which is traveling at the same rate, no matter what conditions or attractive influences may have its path. At the same time, the direct measurements are so great that they may be of great service, and this method employed by several observers with great success.

For strong currents, instead of a tangent galvanometer, Professor Trowbridge, of Harvard University, employs a galvanometer in which the current is capable of turning about a horizontal axis, passing through the center of the needle. When the coil is vertical, the deflection is a tangent galvanometer; but on turning the coil through any angle, the part of the current which deflects the needle will be diminished, and the current has very little effect in turning the coil when the coil is near the horizontal position.

2. *The Electrometer Method.*—The difference of potential between two points in a circuit may be measured directly by an electrometer like Thomson's electrometer, or by balancing the electrostatic forces between the two points, by a balance. The same electromotive force, in the circuit, when a galvanometer is placed, in which the electro-motive force is found by finding

of using Thomson's Electrometer.—potential of the needle, and  $V_1, V_2$  of the quadrants and  $d$  the deviation,  $k$  being a constant, then

$$k(V_1 - V_2) \left( V - \frac{V_1 + V_2}{2} \right)$$

needle and one pair of quadrants be

$$\frac{k}{2} (V_1 - V_2)^2, \text{ where } V = V_1$$

deviation is proportional to the square of the difference of potential, and is therefore of the direction of the current.

If two electrometers so arranged, the energy expended between any two circuit may be at once determined. In the case of a continuous current, the electrometer have its poles attached to two points of the circuit where the potentials are  $V_1$  and  $V_2$ , having a resistance  $r_1$  between them, then

$$Cr_1 = V_1 - V_2.$$

At two other points, C and D, in the same circuit, there is a difference of potential  $V_3 - V_4$ , and having an electromotive force,  $E$ , and a resistance  $r_2$  between them, then

$$E + Cr_2 = V_3 - V_4.$$

The energy expended between these two

$$Cr_2 = \frac{(V_1 - V_2)(V_3 - V_4)}{r_1}$$

The reflection of the two electrometers will be

$$\text{expended} = \frac{2}{r_1} \sqrt{\frac{d_1 d_2}{k_1 k_2}}.$$

The electrometer gives the current, and the two work expended.

If of a continuous current, we have currents succeeding one another at short intervals, which are very short compared with the time of deflection of the needle, then the needle is steadily deflected at a deviation proportional to the mean value of the square of the potential—

$$d = \frac{k}{2} (V_1 - V_2)^2.$$

Thus the differences of potential must be absolutely at the same instant. This may be accomplished by placing two contact breakers on the same axis of the dynamo machine, so that by both of them contact is made at the same instant some 20,000 times then the two electrometers will give the same results. In place of the electrometer employed to give the strength of current, a wattmeter may be employed, as in Clark's experiment, in which case, it is only necessary to make a contact breaker, and so the arrangement is easily made.

The variation of the current in alternate currents may be obtained by the law of the resistance for different periods of time for different phases of rotation of the current. Thus the different phases of the

current may be studied by dividing the period into a certain number of equal parts, and, by means of the contact breaker, making contact only at the same phase of the period of revolution.

The intensity of the light at the different phases of the period may also be studied and measured by means of revolving discs with holes in them, arranged so as to let light through only at the proper instant. The result of experiments is that the law of increase of current in alternate current machines is the law of simple harmonic motion, but the maximum effect does not occur at the normal position, but is displaced in the direction of the motion. Experiments, of which a full account has been given in *La Lumière Electrique*, have shown that even with coils alone there is a retardation of the inductive action arising from the induction of a current on itself. The retardation is about  $\frac{1}{4}$ th of the whole period, even with a bobbin without a soft iron core, and this displacement is independent of the velocity, and rigorously the same for 400, 700, or 1,000 turns in a minute. In the case of magneto-electric machines, there is a retardation which is usually attributed to the retardation of magnetisation of the magnet, but that does not apply to the case of coils, in which case the retardation depends on the self-induction of the current. By the above method, the fall of potential between the carbons in the arc may be measured at different phases of the period of revolution. Thus it is found that at the instant when the circuit is made there is no difference of potential, but in an indefinitely short time the electromotive force rises to 40 or 45 volts, and remains at that value almost without change until the current again becomes very feeble, and then the electromotive force suddenly falls. The difference of potential in the arc seems to be constant within very wide limits for the values of the current. The conclusions arrived at by M. Joubert are that the resistance of the arc is very small; that it varies with temperature and diminishes as the temperature increases. The difference of potential between the two carbons is due to an electromotive force, which is independent of the current, and which is estimated by him at 30 volts. Particles pass between the carbons just as between the electrodes in a volta-meter. There seems to be an action like polarisation, and the work done depends only upon, and is proportional to, the quantity of electricity which passes.

Another method of measuring the currents which is applicable to both continuous currents, and to obtain the average values of alternate currents, depends on the development of heat in an electric circuit. It was shown by Joule, and follows from the law of transformation of energy, that the heat developed by a current  $C$  in a resistance  $r$  in time  $t$  is  $C^2 r t$ , hence the current  $C$  may be measured by the quantity of heat received in a given time by water, in which a resistance  $r$  is immersed. This method has been employed by Dr. Siemens, and was one of the methods employed by Dr. Hopkinson in measuring electric light currents.

In his experiments, Joule inserted a wire of known resistance in a given quantity of water placed in a calorimeter, and measured the change of temperature of the water, and also measured the current, and found that  $H = C^2 r t$  where  $H$  is the quantity of heat produced by the current,

*The Electro-Dynamometer Method.*—There is still another method of measuring currents, which Maxwell says, "is probably the best fitted for absolute measurements."

In Weber's electro-dynamometer, one coil is suspended within another, by means of two fine wires, through which the current is led to the suspended coil. This arrangement is not suitable for powerful currents, because shunts become necessary, and because the suspended wires become heated.

An electro-dynamometer on the same principle has been devised by Dr. C. W. Siemens, who has kindly lent me one of his instruments for these lectures.

SIEMENS'S ELECTRO-DYNAMOMETER.

Attached to a binding screw (3) is one end of a fixed coil or bobbin, across which a single turn of copper wire with its ends dipping into two mercury cups, is freely suspended in a vertical plane, so as to turn about a vertical axis. One of the mercury cups is electrically connected with the binding screw (1) and the other with one end of the fixed coil, so that between 1 and 3 the same current passes through the fixed coil and suspended wire. When the current passes, the suspended wire tends to turn about a vertical axis, but its motion is counteracted by a torsion spring, to one end of which the wire is attached, the other end being fixed to a socket carrying an index, which must be

moved over a graduated circle, so as to suspend wire back to its initial position. The action between the currents in the coils for the torsion which measures it, is proportional to the square of the current. By increasing the number of turns in the fixed coil, and by one turn in the suspended wire, the action of the earth's magnetism on the current in the wire may be neglected in comparison with the action of the fixed coil upon it, so that the deflection of the plane of the magnetic meridian at the time of observation may be disregarded in the use of the instrument. There are usually two fixed bobbins; one coil, attached to binding screw (1), being of a small number of turns of thick continuous currents, and the other, attached to binding screw (2), being much longer and for use with machines giving alternate currents of high tension.

HILL'S ELECTRO-DYNAMOMETER.

An electro-dynamometer has also been devised by Professor Trowbridge, of Harvard University, in which there are two large fixed coils from copper bands, between which is a small coil with a torsion head and connections, so that all the current passes through each coil. This instrument has been used by Mr. W. N. Hill, who limits the deflection of the central coil, and measures the current by bringing the coil back to its zero position by balancing the force of repulsion or attraction by weights placed in two scale pans on each side of the instrument, so as to measure the action of the current by torsion of the suspending wire. If  $c$  be the current,  $w$  the

the weight  $w$ ,  $g$ , and  $g$  the constants  
coils, and  $k$  the constant of the instru-

$$= \frac{lw}{kag}$$

was found by measurement, and  $k$  is found  
reason with another instrument. Through  
of Messrs. Elliott Brothers, I have  
tunity of bringing before you an electro-  
meter of this form with the latest improve-  
This form of dynamometer is especially  
for large currents, since the weights re-  
bring the deflection to zero increase as  
re of the current, and so greater accuracy  
obtained.

we blocks illustrating this lecture have been  
x, that of Siemens's electro-dynamometer by  
tor of *La Lumière Electrique*, that of Hill's by  
of the *Electrician*.]

## MISCELLANEOUS.

### POST-OFFICE REPORT.

nty-seventh annual report of the Postmaster-  
is just been issued, from which the following  
have been taken:—

#### LETTERS.

umber of letters delivered in the United  
during the 12 months was 1,176,423,600,  
n increase of 4.3 per cent.; the number of  
, 123,584,900, an increase of 7.4 per cent.; the  
book packets and circulars, 248,881,600, an  
16.3 per cent.; and the number of news-  
33,796,100, an increase of 2.6 per cent.  
gain a marked increase in registered letters,  
re recorded being 10,034,646 against 8,739,191  
rious year, or an increase of 14.8 per cent.  
achinery of the department has necessarily  
ided; 437 new sub-offices have been opened,  
so total number of such establishments to  
rich with 912 head offices, makes the grand  
et-offices 14,549. About 620 letter-boxes have  
d, and the number of receptacles of all sorts  
may be stated at 27,709.

undred officers have been added to the force,  
the 31st of December last, had reached a  
ailing all grades, of over 47,000 persons, of  
s 2,000 are women. The success obtained in  
women as clerks in the Savings-bank and  
er and Accountant-General's Office has led  
umber being considerably increased. Hitherto  
as have been appointed upon a plan of limited  
n, three being nominated to compete for each.

In future, however, the appointments will  
through open competition, subject to rules  
the Civil Service Commissioners. Another  
extension of the principle of open competition  
carried out, male and female telegraphists in  
Edinburgh, and Dublin being now appointed  
y. The health of the 10,900 officers employed  
a has been generally good; the death-rate,  
low, has fallen to a point below any previously  
the actual number of deaths in London being  
a rate per 1,000—4.1.

the incidents of the year may be mentioned  
as of extraordinary violence, which, impeding  
communication, and severely taxing the energies  
ernment, occasioned large additional expendi-  
the 18th of January no night mail could be  
i from London, and on Friday, the 4th of

March, five carriages were blocked in the snow in Scot-  
land, and were not extricated till the following Monday,  
while the Sutherland and Caithness Railway was com-  
pletely closed for a fortnight. However, during the  
whole period of the storm not a single mail bag was  
lost, nor, throughout the year, did any accident occur  
involving the loss of a life engaged in the postal service.  
A letter containing a £1,000 cheque, which should have  
been posted in Lombard-street on the 18th of January,  
was found on the 24th in the Thames near Deptford,  
among some snow drift which had evidently been carted  
from the City and thrown into the river. The letter,  
which had never passed through the Post-office, was  
duly returned to the sender. During the Christmas  
week more than 11½ millions of letters and packets, over  
and above the ordinary correspondence, and four tons of  
extra registered letters, representing a total postage of  
nearly £58,000, passed through the central office. To  
meet such extraordinary pressure the services of volun-  
teers from other departments of State were obtained  
after office hours, and the assistance thus procured was  
found most valuable.

Over 5,300,000 letters were dealt with in the Re-  
turned Letter Office, 478,000 of which it was found  
impossible to deliver or return. One contained a bank-  
note for £100, still unclaimed; and attached to the seal  
of another was a sovereign, which was returned to the  
owner, who had forgotten to remove it. In addition  
to the letters, about half a million of post-cards, four  
million of book packets, and 400,000 newspapers found  
their way to the same offices. More than 27,000 letters,  
an increase of 3,000 over last year, were posted without  
any address whatever, 6,000 furnished no clue to the  
sender, and 1,340 contained articles of value to the  
amount of nearly £5,000. The use of too fragile covers  
occasioned the escape of some 30,000 articles, and, no  
doubt, entailed much disappointment. The habit of  
transmitting animal and perishable matter, such as  
fish, sausages, birds to be stuffed, clotted cream,  
fruit, yeast, salads, jellies, live kittens, and dead rats  
still prevails; and it is necessary to appeal to the  
public to discontinue a practice so injurious to the health  
of the officers in one branch of the department, and to  
repeat the warning that such forbidden articles will be  
stopped. The return of a letter, posted without an address,  
to a firm whose direction appeared within, led to the dis-  
covery of a systematic robbery of goods and the appre-  
hension of the offenders. At Hull, an incident occurred  
proving the elasticity of the postal organisation under  
heavy pressure. The distribution of nearly 300,000 cir-  
culars, weighing 20 tons, issued by a single company,  
and representing £3,380 worth of postage, was effected  
without confusion or delay in 48 hours. The despatch  
necessitated the employment of seven extra railway  
vans, and it is believed that all the documents duly  
reached their destination.

#### PARCEL POST.

In October last a Postal Conference, attended by the  
Secretary of the Department, and Mr. Bonthall, one of  
the Assistant Secretaries, was held in Paris to consider  
the possibility of establishing an International Parcel  
Post. After much discussion, an agreement was arrived  
at providing for the transmission throughout almost  
the whole of Europe of parcels not exceeding three  
kilogrammes (about 6½lb.) in weight at very moderate  
charges. It was, however, impossible for Great Britain  
to sign the treaty which embodied these conclusions  
without having previously established for herself an  
inland parcel post.

#### TELEGRAPHY.

The telegraph business of the United Kingdom  
continues to increase; the messages sent were more  
numerous by 3,419,828 than in the previous year, and  
the aggregate reached 29,966,966. During the year  
107 new offices were opened, and the total number now  
stands at 5,438. The new main line from London to

had established exchanges, but after much negotiation an agreement was concluded which, while protecting the interests of the public, afforded reasonable advantages to the companies concerned. The system of telephonic intercommunication is, therefore, now being extended partly through the agency of companies and partly by the Post-office. The Department has in course of completion telephone intercommunication systems at Swansea, Glasgow, Greenock, Hull, Manchester to Liverpool, Newport to Cardiff, Leicester, Sunderland, and other towns, and is receiving applications from many quarters.

#### SAVINGS BANKS.

Much has been done during the year to encourage thrift. On the 22nd of November, 1880, an Act came into operation by which any person desiring to invest any sum between £10 and £100 in Government Stock can do so through the agency of a savings bank at a trifling expense, varying from 9d. to 2s. 3d., and have the dividends collected free of further charge. The purchase can be effected either by transferring money from the depositor's account, or by means of a sum specially deposited for immediate investment. Between the 22nd of November and the 31st of March the amount thus transferred through the Post-office Savings Banks was £151,465, and the amount specially deposited, £230,874, making an aggregate of £382,139 invested by about 6,300 persons, and it is satisfactory to notice that the sales did not exceed £7,600. The stock certificates with coupons payable to bearer, obtained under Section 3 of the Act, were, in the period stated, 63 in number, and £4,950 in amount. Notwithstanding the channel thus opened, the total amount of deposits, with the interest due, had, on the 31st of December, reached £33,744,637, showing an increase of £1,732,503 over the amount recorded on the corresponding day of 1879. The Post-office Savings Bank year, prescribed by statute, terminates on the 31st of December, but comparing the financial years ended 31st March, the result obtained is:—The total amount of deposits on the 31st of March, 1880, including interest to previous 31st of December, £32,578,406; the total amount of deposits on the 31st of March, 1881, including interest to previous 31st of December, £34,782,329; estimated increase in the financial year ended the 31st of

years. The total amount, including depositors on the 31st of December last, being £138,500 in excess of the total year, exclusive of a sum of £17,000 in Government Stock. The names of about 10,000 were added, and the proportion to 65, as compared with 1 in 74 in 1879. Ireland contributed its quota, and the eight counties scheduled as districts £8,448 over and above the growth of—viz., £33,866 against £25,418.

#### POSTAL ORDERS.

Under the provisions of the "P.O. Act, 1880," a new system was introduced in January, providing an inexpensive means of sending small sums of money to different parts of the United Kingdom. This Act was introduced in the previous Session. Drafts, entitled postal orders, are bought, at any money-order office, for varying from 1s. to 20s., subject to a minimum of one halfpenny to two pence. 646,989 of such orders were sold of the producing commission to the amount of £1,000,000. It is evident, from the increasing number of public appreciate the convenience. The decrease in the number of remittances, which commenced in 1878, the inland orders recorded show a 27 per cent. in number, and a 2 per cent. in amount as compared with the previous year. The result is no doubt attributable to the facility of transmission by other means, as letters and postal orders. The number of large amounts increased, and the foreign business exhibits a steady progress. The diminution in the number of inland orders transmitted for the public was 2,000,000 sterling, and the losses by fraud and error exceeded £215. It will be seen that the gross amount, as compared with last year, made up by the amount of postal orders, and it may be expected that the new methods combined will eventually produce a considerable increase in the amount for the year.

cent. on the capital, and leave a real 62 towards the cancelling of debt.

observed that, in consequence of the funds being vested in the National Debt, no allusion is made in the accounts to and expenditure of the Savings Bank but the Postmaster-General adds the particulars:—The expense of conducting business during the year was £180,891, than in the previous year. This apparent expenditure at a time when there was a of business was, in a great measure, due to the proportion of the cost of the new building in Queen Victoria-street charged to was much less than that charged to year. The net profit paid over to the National Debt Commissioners was would, therefore, appear that the real enditure was £5,629,556, and the revenue 1, showing a profit of £3,071,525.

## OLD MINES OF SOUTH INDIA.

ig is an abstract of a report on this subject by Mervyn Smyth, which was printed at March of the present year:—

h Smyth, speaking of the extent of the ig region in the Wynaad, says:—"Gold l in the South, near Eddacourra; on the Nellacottah; on the West, near Vyteri; East, as far as Bolingbroke, that is to say f more than 600 square miles." (Report s, p. 61.) Of this area, native workings fined to Devalla and its vicinity, a mere e country indicated; and even here the o magnitude, the deepest shaft being 70 longest adit 126 feet; and yet it is from s as these, within those narrow limits, we believe that such enormous quantities of following, were obtained:—"B.C. 1000. to Solomon by way of the Red Sea— weight. A.D. 1294. Ransom paid to eneral of Jalalu'din Khilgy, Emperor of e Raja of Deoghar—17,500 lbs. of gold. rt of spoil of Devara Samudra (Halabid, ented by Malik Kafur, to the Em- dli—2,400,000 lbs. of gold. A.D. 1309. s of Kales Dewar, Rajah of Mabar s of gold, equal to 1,200 millions sterling or s. of gold."—(Gold in India.) That India duced this enormous quantity of gold obable, as witness the yield of the nes from 1851-68, viz., 147,342,767 pounds what we may well doubt is that all this have been derived from the Wynaad. t which strikes one, and which goes to e Wynaad could not have been the locality ll this gold was obtained, is the singular ns of cities, temples, &c., and the presence forests of vast extent. One would imagine such immense wealth came from, *there* cations of its influence, in the shape of great mples, tanks, cultivation, and other signs t, be most common, and that such would l result of unprecedented wealth we see n the rapid growth of those marvellous ancisco and Melbourne—that have sprung rness far more desolate than the Wynaad. t suggests itself is, if we are not to look ad as the spot from whence this large old was derived, where else are we to look? t that all the necessary requirements are xamination of the country forming a great ico sides may be indicated by the Eastern River Kistna, and the Western Ghats;

and this country was known as Mysore at the death of Hyder Ali in A.D. 1782—a region whose geological aspect is similar to that of the gold-bearing regions of America and Australia. Mr. Eastwick, in an article in the "Gentleman's Magazine" for January, 1880, mentions as one of the facts illustrative of the abundance of gold in Southern India, part of the spoil of Dwarasamudra, amounting to 2,400,000 lbs., presented to the Emperor of Delhi, by Kafur, his successful general. The ruins of this city are to be seen in the vicinity of Halebid, in the Hassan district, Mysore. It is said to have been destroyed shortly after its capture by Kafur by another of the ruthless Mahomedan invaders. The splendid temples still in existence speak of the great wealth of this place. Of the wealth derived from India by Solomon it will be sufficient to say that many of the incidents recounted in the Ramayana, B.C. 1300, show that Mysore was at that time in a flourishing state. Among great cities of more recent date may be mentioned Ikkeri, Shemoga district (A.D. 1640), where gold pagodas and fanams were coined, many of which are still to be seen in the Mysore country, Bednur, or Nagur, at the capture of which place Hyder was said to have obtained twelve millions sterling. Here he established a mint where gold coins—Haidari pagodas—were struck in his name. Vijayanagar (A.D. 1565) identified with Hampe in the Bellary district. Abdul Razzak, who visited it in 1441 as ambassador from the court of Persia, speaking of its wealth, says—"In the king's treasury are chambers with excavations in them filled with molten gold, forming one mass. All the inhabitants of the country, whether high or low, even down to the artificers in the bazaar, wear jewels and gilt ornaments in their ears and around their necks, arms, waists, and fingers." It will be presently shown that all these cities were situated in or near districts known to be auriferous in the present day, and where may be seen ruins of mines of great extent. Of the N. and S. Ponaar (*Pon*—gold, *aar*—river) it will be sufficient to mention the villages of Nulloor and Coondoor, on the former, and Utchalam and Poonpillay, in the Salem district, on the latter, where gold-washing is carried on to the present day. On the western coast gold is found in the Gungavally and Gairsoppa rivers, N. Canara, and in the Beypore river, in Malabar. The auriferous reefs and old workings of the Wynaad have been reported on by Mr. Brough Smith, while those of Kolar have had more than justice done them by such men as Mr. Munday, Mr. John Harris, Professor Vazie Simon, &c., who have examined them on behalf of different companies. But it is not to these localities alone that auriferous reefs are confined, but scattered all over the whole area are gold-bearing reefs and old mines, some of the latter of far greater extent than any to be found in the Wynaad or Kolar, and it is believed that no spot within the boundaries mentioned can be indicated, which is more than 50 miles from the nearest ancient working. Immediately south of Kolar is Baramahal, in the Madras Presidency, wrested from Tippoo in 1792. The greater portion of this district is made up of low hills, from 1,500 ft. to 4,000 ft. high. In the northern part of this district are the Jaghire of Bagalur, Beriki, Sholagherry, and Kangundi, the mining rights of which have been purchased by several companies. About ten miles west of the Coopm Railway Station is a singular looking conical hill, rising about 600 ft. above the surrounding country, and about 200 ft. above the remainder of the ridge, which runs north and south, for about 15 miles. The top of this peak terminates in a boss, which overhangs on its S.W. side and gives it a conspicuous appearance, so that it can be recognised from miles off. This hill is known as Mallapakondah, and is situated in the Kangundi Jaghire, Salem district. Half-way up this hill, and on its southern face, is the entrance of an adit driven into the heart of the hill. It would appear that there were originally several of these drives at different levels, and the topmost is now filled in with

allowed of so expensive a pathway being constructed. The quartz is highly ferruginous and dark coloured, dense in centre and cavernous where it joins the casing—the latter a kind of vitrified slate. The principal reef is about 10 ft. wide, and on either side are smaller reefs, from 2 ft. to 2 in. Sulphate of iron is apparent in some of these, and it is not difficult to collect flowers of sulphur in small quantities. No gold can be seen in the quartz by means of the naked eye, but a small piece of a few ounces, crushed and washed, gives innumerable grains of fine gold. It is not necessary to choose a particular piece of quartz; any bit from the *débris* lying about may be tested with good results. Two miles south, and on the same ridge, are two other mines within half a mile of each other. The more northern, called "Goolgunt," consists of three circular shafts sunk at the angles of a triangle, whose side is 50 ft. The shafts are connected by passages at about 40 ft. from surface, but it is impossible to tell their extreme depth, owing to the large quantities of water in them. Great heaps of *débris* testify to the amount of material that must have been excavated. Half a mile S.E. is the "Chigargunt" mine, the entrance to which is by means of two shafts, each about 7 ft. wide and 20 ft. long. The upper shaft is about 60 ft. deep, and at one end is a narrow man-hole (just large enough for a small man to wriggle through), leading into the adjoining shaft, which is fully a 100 ft. from surface. At the bottom of the deeper shaft are two adits, running N.W. and S.E. along the strike of the reef. Great numbers of rock pigeon have taken up their abode in these mines, and eggs innumerable and young pigeons are seen in the clefts of the rock. The great heap of excreta of these birds (not less than 20 ft. in height) testify to the age of these mines. The whole of the rocks below are coated with chloride of ammonia (sal ammoniac) from the urine of the pigeons. The quartz is of a yellowish white colour, and pyritous, and is extremely hard, as is the casing, and it is wonderful to think how the natives could have cut through such dense stuff with their primitive appliances. One sample containing visible gold was chipped off from a leader 100 ft. from surface. Two miles further south is another large mine called "Nundymoduk" or "Baswana." The natives say that this mine is of great extent, but the water with

of fortifications are to be seen, one the top of the hill. Within the topography is a large cave running some distance of the hill; and within this cave, the mint of Ballala Raj was constructed. say, when after heavy rain, water mouth of the cave, small gold coins picked up. This locality, with its numerous affords ample materials for the several miles south from this place, were worked by Tippoo, in the Kollegal district. These mines, as well as the Taluk of Chamrajnagar, Mysore filled in, it is said, by Tippoo, and the neighbouring villages deported, hence of these workings reaching English, under Lord Cornwallis, were from this direction. The mines are of great extent and of much is from this region that all the gold common at Manipur is supposed to have been obtained from this direction. Land for mining purposes in the Kollegal has been applied for, by the Indian Companies. Thirty miles to the south of the Neelgherries, where there is of some extent at Nunjanad, described by Smyth in his report on the Wynad. have the gold fields of the Wynad. Skirting North Wynad is the Hegg Mysore Territory, where gold is found in the streams. ("Mysore Gazetteer," Still further north, in the Attikup the gold field of Chinnatagery, near mines are reputed to have been of gold have been worked out. The famous—the richest in Mysore—is said to be the wealth derived from these mines few washers are just able to earn a pice by sifting the sands of the reef during the monsoon. The late Maharaja made an attempt to work these fields with a set of native miners for about a month were obtained, the attempt was a failure twelve years ago several samples of this locality by Col. Hill, of the Madras Army, with a request that they might be sent to the Mint for assay.

nation of the low slate hills to the west of id, and so far north as Sakarapatam will show, they are in some places actually honey-combed mines, some in good preservation, others filled in *lebris*. Every stream about these hills gives a yield of gold, showing that their auriferous is far from exhausted. In the adjoining Taluq anhalli, are numerous mines and old workings, common was this metal during the reign of the Ballala kings, that a local tradition has it that sculptors employed on the famous Halebid temple, paid in gold equal in quantity to the dust resulting from the tooling of those "marvellous elaborations of mental sculpture." There may be some truth in tradition, as even the price alleged to be paid to artisans would not be too much for work that has forth the following eulogium:—"Some of these carved (on stone) with a minute elaboration of which can only be reproduced by photography, may probably be considered as one of the most illustrious exhibitions of human labour to be found, in the patient East." ("Fergusson's Architecture," p. 397.) These temples are computed to have cost millions sterling. Seventy miles due west Halebid, and in the South Kanara District, are the celebrated diggings of Moondabetta, miles south of Mudu Badari. Here, too, man enterprise has stepped in, and after one or two failures is now in a fair way of success. East from this we have the Honnali fields in the Sagar District. Of the richness of these fields we judge from the following official communication Mr. W. Hill, Deputy Commissioner of the Shemoga District, to the Commissioner of the Nagar Division, respectively November 16 and December 16, 1878:—"Only place in the district where gold is to be found Nulka near the village of Pulvanhulle in the anhalli margin of the Honnali Taluq. It appears gold dust was formerly obtained by washing the sand of the nulla. The right to do so used to be farmed under the head 'Juglar,' but this item of revenue abolished in 1870. *Vide* Isthiar, dated 28th November, 1860, the amount of contract realised was—58, Rs. 357 8 a.; 1858-59, Rs. 264. Since then the weight is brought weekly to the market at Nulka for sale by the juglars (sifters)." "Since my letter, No. 763, of the 16th ultimo, on the subject of the right to wash out from the sand, or rather alluvium, of the Pulvanhulle stream, three miles south of Nyamti, the honour to report that I have been able to visit the spot and gather the following further particulars:—(2.) The number of men who gain a livelihood by washing the gold is about 20. Their number formerly greater, but several have been attracted to the last ten years to a hill called Bijari Gudda, Karkal in South Kanara, where the finds are said to be greater and the work more remunerative. Work is done in Pulvanhulle mostly in the rainy months, regular workers are said to be able to earn as much as 50 in the season. Once and again small nuggets are met with. The largest found was about ten years ago, 1 oz. 14 dwts. 6 grs. in weight; another, more lately, of 1 oz. 5 dwts. 17 grs.; and a third, accidentally to an outsider, of 1 oz. 1 dwt. 10 grs. in weight. The quantity of gold bought annually in Nyamti and neighbourhood is said by the traders to be 1 lb. 11 oz. in weight, of the value of Rs. 800. I beg to forward a small specimen of the gold, valued at Rs. 5, which was obligingly returned if not bought for the same, also some black ferruginous sand with minute particles of gold (of the value of As. 3), such as is commonly found by the washers. The process followed is very simple. They dig up the loose gravel (alluvium) in the bed and sides of the stream, and washing a quantity of it in a small trough, on a slight slope, wash the earth out about three or four times, and cast the heavy stones away, till only the light black

sand remains. This they put into a hollow, flat, round, wooden dish, sift it, if the particles of gold are visible, after which they gather them together with the use of mercury, which, being volatile, is afterwards easily separated. The diggings are not confined to the Pulvanhulle stream, but to all the minor streams flowing from the hills in the neighbourhood. One of the best is said to be the Surhona stream, near Devikopa, a little off the Kumai Honali road, about three miles N.W. of Nyamti, and about the same distance from Pulvanhulle. The chief drawback to its being worked is the want of water. The Jalagars (washers) informed me that they were well aware that gold was dug up from pits in Kanara, but they explained that it would be useless to attempt it here, as veins of gold were not found embedded in the quartz. I forward specimens of the quartz, slatey rock, gravel, and hematite (iron stone) picked up by me at the heads of the streams from which the gold is washed down. They may be of assistance in enabling Mr. Brough Smyth, with the foregoing information, to judge whether it would be worth while to take the trouble of inspecting the locality. Evidently the prospects of finding richer veins in South Kanara are greater." It is a noticeable fact in Indian polity, that where a handicraft has been confined to a family, or set of families, for a lengthened period, the people who practice the calling are identified with it, and it becomes a caste distinction, as much as the well-known four great divisions of Brahmin, Kohetria, Veishya, and Sudra. The goldsmith is as much distinguished from the weaver as the Veishya from the Sudra, while the barber and shoemaker have but little in common beside their humanity. Now, in Mysore, we have the well-known caste of juglars (gold washers), not very numerous at present, perhaps, yet so well known that the commonest rhyot can tell whom you want when you ask for a juglar, thus showing how common the calling must have been at one time. They are to be found in some numbers in the vicinity of known auriferous localities throughout Mysore, and their presence is, in a measure, indicative of the richness of the reefs there found. One other fact which goes far to prove that gold was commonly found in the country, is to be seen in the geographical nomenclature of the province. Scattered all over this area are rivers, hills, towns, villages, and even whole districts, whose names are made up of a prefix, meaning gold, and a distinguishing terminal. It is not to be expected that so important a mineral as gold would have escaped the attention of the various races who have at different periods conquered the country; and that it did not may be learnt from the fact that we have Sanscrit, Tamil, and Kanara expressions, meaning gold, to designate places from whence this mineral was obtained. Thus the Sanscrit for gold is *suvarna* and *hemma*. So we have the rivers Survana-mukhi (gold-face) in the Kolar district, and Survana-vati (gold-feature) in Chamrajnuggar, and the village of Survana in the Honali taluq. Shemoga; Hemavati, a tributary of the Cavery, and Hemagiri (gold-hill), a large bund across this river in the Narsipur Taluq. In Kanara, gold is *Honna* and *Chinna*, and we have Honnu-Hole, Honnali, Honnavalli Honni Kambli, Bhatta, Honavar, and Chinnagherri. In Tamil we have Ponaar, Penoor—*pon* being Tamil for gold.

#### PUBLIC INSTRUCTION IN THE PROVINCE OF BOLOGNA.

Consul Colnaghi states that the law of compulsory instruction passed by the Italian Parliament in July, 1877, has with satisfactory results been put in force in the commune of Bologna, where nearly the full complement of children required by law to be under instruction are present at the schools, with the exception of the mountain and country districts, where material

has been introduced in the schools of the commune of Bologna as well as in those of Imola, San Giovanni in Persiceto, S. Giorgio di Piano and other districts. Elementary gymnastic movements performed in school time on the benches are carried out in all the schools of the province. The number of schools in the province of Bologna in the year 1878-9 was 46, in addition to which there were 215 public evening schools for adult males, and 192 public fête day schools for adult females. Of the masters engaged in teaching at the evening schools, 6 are ecclesiastics, and 209 laymen, 210 hold permanent, and 5 provisional diplomas. Of the mistresses of the fête day-schools, 183 are provided with permanent, and 9 with provisional diplomas. The evening schools are open only during the winter months, the fête day schools during the whole year. In addition to the municipal grant there is a Government subsidy of 16,350 lire to be divided among the 407 teachers in the proportion determined by the provincial scholastic council. For secondary classical instruction the city of Bologna possesses a royal Lyceum with 101 scholars, a communal gymnasium with 235, an archiepiscopal seminary (lyceum and gymnasium) with 93, a private lyceum and gymnasium with 91, and two other private gymnasia, one with 76 and the other with five scholars. The city of Imola contains a communal school with 54 boarders and "externes," and an episcopal seminary with 24 scholars. Secondary technical education is given in two communal technical schools, one divided into two sections at Bologna with 330 inscribed scholars, and the second at Imola with 63. Bologna maintains an upper female school with 76 pupils, 30 in the preparatory class and 46 at the school. There are two Government normal schools for the instruction of masters and mistresses for the elementary schools; they are provided with 22 teachers, and are attended by an average of about 200 students. For higher education the celebrated University of Bologna still flourishes, and maintains a good reputation by the assistance of distinguished professors; it contains four faculties—jurisprudence, medicine and surgery, mathematical and physical sciences (to which a school of application for civil engineers, maintained in part by the Government and partly by the municipality, province, and other institutions has been added), and philosophy and letters, with various minor classes, and is frequented by about 500 students. The Royal Technical Institute at

period half was to be devoted payment of a school attached to the teaching mathematics applied to to reward any inventions that might in connection with art, industry, or other half is to be placed at another period of thirty-one years: division is again to be gone through of the property will take place this lire will be available for the year 1911, the amount to be divided will 1941, 1,435,902 lire, and so in a ratio. If the commune of Imola the wishes of the testator, the commune of Bologna.

## GENERAL NO

**International Medical and Sanitary Exhibition, 1881.**—This Exhibition, organised by the Parkes Museum, was closed on Saturday when the number of visitors, exclusive of holders, was 1,221, making a total of four weeks during which the Exhibition allowing for one visit only by each. The closing of the Exhibition was at the St. John Ambulance Association, tion of ambulance practice, and during number of the visitors assembled in witness the practice. Prizes were won by the Grenadier Guards, the Finsbury I. Police. It is expected that the design for the diploma was entrusted who has produced a composition, in the female figure, representing Sanitary a boat, in the act of casting out a life.

**Electric Lighting.**—The station now lighted by the Crompton electric lamps within the station, platform, and six above the departure of a larger size are placed on the outer extreme corners of its front. It from five Burgin dynamo-electric a steam-engine of 12-horse power now

## GASTON LECTURES.

## THE FUNDAMENTAL PRINCIPLES INVOLVED IN ELECTRIC LIGHTING.

Lecturer W. Grylls Adams, F.R.S.

L. III.—DELIVERED MONDAY,  
MARCH 21, 1881.

*On the principles of the dynamo-electric machines for  
lighting.—Electric lighting by means of the*

fundamental principles which underlie all electric machines are the four great principles first enunciated by Oersted, in 1819, by Ampère in 1820, and by Faraday, in 1831. In 1820, Ampère discovered the action of a current on a magnet. In 1820, Ampère discovered the action of magnets and currents on each other in their neighbourhood, and in 1820, Ampère showed that currents of electricity induced magnetisation, thus laying the foundation of electro-magnetism; and in 1831, Faraday discovered that induced currents were produced by the motion of magnets. All machines for the conversion of work into electricity are based on Faraday's great discovery of the induction of currents from the relative motion of a coil of wire.

Electric machines are divided into two classes according as they furnish continuous or intermittent currents. All such machines as far as regards the currents in the external circuit are made to flow always in the same direction, in constant machines, by means of a commutator which reverses the contact at every half-turn.

The machines of Pixii, in 1832, followed by those of Saxton and Clarke, were the first continuous current machines. From these we may pass to Wheatstone's introduction, in 1845, of electro-magnets in place of permanent magnets, to produce the magnetic field. In 1854, Messrs. Werner Siemens and Halske introduced the Siemens armature, in which the coil is wound longitudinally in a groove. The strength of the continuous current depends on the velocity of rotation, on the length of the wire, and on the power of the magnetic field formed by the magnets.

It is remarkable that, in 1854, Hjorth originated an idea which was some 13 years in advance of his time; he patented an improved magneto-electric battery, in which the currents induced in the revolving armature pass round the electro-magnets, and increase their magnetism, and so increase the induced currents at compound interest rate. This was the celebrated principle afterwards re-discovered by Siemens and by Wheatstone simultaneously in 1867, which has formed the basis of all dynamo-electric machines, and which, for equal power, are cheaper and more compact than all other magneto-electric machines.

## DYNAMO-ELECTRIC MACHINES.

In February, 1867, Dr. Siemens and Sir Charles Wheatstone, on the same evening, presented to the Royal Society their two papers, "On the augmentation of the power of a magnet by the reaction thereon of currents induced by the magnet itself." According to the principle then put forward by Dr. Siemens, the rotating armature, the electro-magnet, and the external resistance, such as an electric lamp, are joined up so as to form one simple circuit. A small amount of magnetism is communicated to the electro-magnet, so that, on rotating the coil, a current is induced alternately in opposite directions, and after being reduced to the same direction by a commutator, this current passes through the coils of the electro-magnet in such a direction as to make it stronger, so enabling it to react on the armature. Thus the magnet and the armature act and react on one another, strengthening the magnetic field, and continually strengthening the induced currents. Sir Charles Wheatstone put forward the same principle, and called attention to the fact that at the first instant of completing the combined circuit the effects are stronger than they are permanently. The principle of these dynamo-

FIG. A.—DYNAMO-ELECTRIC MACHINE.

The principle of these dynamo-electric machines is clearly shown in the figure A, where N and S represent the poles of the electro-

magnet enclosing the revolving armature, the external resistance in the circuit being represented by an electric lamp. Sir Charles Wheatstone also pointed out that a very remarkable increase of all the effects is observed, when a shunt is employed to divert a great portion of the current from the electro-magnet. By that means four inches of platinum wire, .0067 in. diameter, was made to glow. A certain resistance in the shunt was found to be necessary to produce the best effects, so as neither to weaken the magnetism too much, nor to give the current too much work to do in heating a high resistance.

In addition to this, Sir Charles Wheatstone showed that the effects above described are far inferior to the effects obtained by placing the work to be done in the shunt circuit. Thus seven inches of wire were made to glow in the shunt, when only four inches of the same wire would glow in the original circuit. There is thus a double advantage, for there is no loss of resistance by introducing the shunt, the resistance of the shunt being the resistance on which the useful work is done.

FIG. B.—DYNAMO-ELECTRIC MACHINE.

This improvement, suggested by Sir Charles Wheatstone in 1854, and now being adopted by Dr. C. W. Siemens in his latest dynamo-electric machines, is very well shown in figure B, for which, as well as for the other figures illustrating this lecture, I am indebted to the kindness of the Director of *La Lumière Electrique*.

Wheatstone also showed that the effects are much less influenced by a resistance in the electro-magnet branch than in either of the other branches. Thus, with about four inches of glowing platinum wire in circuit, the addition of about five inches of platinum wire in the armature branch, or in the shunt, produced a  $\frac{1}{2}$ -inch glow, whilst four feet of the same wire was required in the electro-magnet branch to reduce the glow to three-fourths of an inch. Dr. Siemens has shown that, for the greatest efficiency, the resistance of the rotating coil must be small, but the resistance of the electro-magnet may be increased, and that in both cases the wires should not be small, but of considerable diameter.

#### THE GRAMME RING.

In the Gramme armature, coils of wire are wound in sections, all in the same direction, round a ring; and each section, when a current is flowing through it, may be regarded as an electro-magnet. The similar poles of all these sectional electro-

magnets will point in the same direction round the ring. Consider only one of these magnets with its north pole directed to the south pole of another magnet, it will be towards it, and with greater and greater nearer it approaches; on passing the south pole of its own south pole will be presented to the pole of the fixed magnet which it has just passed, and its motion will be continued in the same direction.

Now, suppose no current to be flowing in the ring, then, on applying force to produce motion as before, the induced current will flow in the opposite direction, i.e., as the coil approaches the south pole and past it, the current in the coil is round the ring, as if from behind, in the direction opposite to the motion of the hands of a watch.

With right-handed winding of the ring like a cork-screw, the current flows towards the observer, or in the opposite direction to the motion of the ring on the side nearest the south pole.

If we consider a section of the ring approaching and goes away from the north magnet, the induced current in the ring, as the observer looks at it from behind, will flow in the same direction as the motion of the hands of a watch. Hence the current will be away from the observer in the same direction as the motion of the side nearest the north pole. Hence the flow is opposite ways round the ring halves of the ring, and meet at points between the two poles.

#### DYNAMO-ELECTRIC MACHINE

When the armature of a dynamo is turned, the amount of work which is done means of it is proportional to the number of revolutions the armature makes per minute. If the same current flows through the electro-magnet and the armature, the current in one acting on the other will attract or repel it with a force proportional to the product of two currents, or the square of the current. The action of the currents is increased four-fold, when in each is doubled. Hence, when such a machine is used as a generator of an electric current for external work which can be done by it in the electric arc or elsewhere is proportional to the square of the current.

#### USE OF SEPARATE EXCITING MACHINE

In all dynamo-electric machines, when the current passes round the magnet and the armature, any disturbance in the resistance of the circuit, in the electric arc for instance, alters the current, and this alters the magnetic field, which again produces a disturbance in the current, so that any disturbance is intensified, just as the permanent magnetism of the iron core is intensified by the current in the machine on itself.

To obtain greater regularity, Wild proposed to employ a separate continuous machine to give a permanent magnetism to revolve the armature of the second machine between the poles of the magnet which is the first machine. In order to find the effective work of these machines, and the

electric lighting or for other purposes, we have from the laws of Ohm and Joule, that elements of current, and of the work done by current, must be made.

In the last lecture I indicated four methods of such measurements, viz. :—

1. The galvanometer method,

2. The heat method, i.e., by the change of nature produced by the current in a wire of resistance.

3. The electrometer or potentiometer method.

4. The electro-dynamometer method, i.e., by the action between different parts of the same  $t$ .

#### EFFICIENCY OF MAGNETIC AND MAGNETO-ELECTRIC MACHINES.

If we take a battery in a closed circuit, we know, from the laws of Faraday, that the amount of work produced is directly proportional to the mass of the chemical elements decomposed in the cells of the battery, the quantity of electricity involved in the battery being a measure of the quantity of current which has passed. According to the laws of transformation of energy, the work done in the chemical actions is here equivalent to the work done in heating the circuit. We may express the energy or the work done by electricity in the same way as we express the energy of water by the pressure multiplied by the quantity of water. The electro-motive force corresponds to pressure, and the current flowing to the quantity of water, so that the work done by the battery is the product of electro-motive force by the quantity of electricity.

The work which can be done in the circuit is where  $E_0$  is the electro-motive force of the battery, and this is spent in heating the resistance.  $E_0 C_0 = C_0^2 R$ , where  $C_0$  is the current induced through a resistance  $R$ . Now, if any part of the circuit, carrying a current, be set in motion under the action of exterior magnetic force or under the influence of the mutual reaction of the currents in the fixed and movable parts, then the equivalent to the chemical actions in the battery will be spent in producing the motion of the conductor, and partly in doing the work of the electro-dynamic or magnetic forces. Denoting the work done in producing motion and the current in this case by  $C$ , we get  $E_0 C = C^2 R + K$ . The work  $K$  is equivalent to the external work done by the current  $C$ . Now, the external work  $K$  gives rise to an opposing electro-motive force in the induced circuit, and the value of this induced current is  $E C = K : R$  : or  $E$  is the electro-motive force due to induction.

The efficiency of an induction machine, when used as a motor, is the ratio of the work  $K$  to the work  $K + C^2 R$ , i.e., the ratio of the electro-motive force of induction to the total electro-motive force of the battery. The efficiency

$$\rho = \frac{E}{E_0} = \frac{K}{K + C^2 R} = \frac{1}{1 + \frac{C^2 R}{K}}$$

effective work  $K = E C$  and  $C R = E_0 - E$ . Therefore,  $K = \frac{E(E_0 - E)}{R}$ .

If, then, a battery of electro-motive force  $E_0$  be employed, and an induction machine be employed as a motor, then the effective work depends on the product of two quantities, one of which increases as fast as the other diminishes.

Now, if one quantity increases as fast as another diminishes, their product is greatest when the two are equal. Hence such a machine is most effective when  $E = E_0 - E$ , i.e., when  $E = \frac{1}{2} E_0$ , so that

$$K = C^2 R \text{ and } \rho = \frac{1}{2}.$$

Half the work of the battery is then spent in heating the circuit, and the other half in doing the external work. This corresponds to the case where the strength of the battery current is diminished by one-half through the effects of induction. If the same machine be employed to produce a current of electricity by applying external work to it to turn it, then the energy of the induced current is equal to the work done by the currents during the motion, or  $K = E C$ . If  $K$  is greater than  $E C$  at first, then the machine will go faster and faster, and  $E$  and  $C$  will increase, until the product becomes equal to  $K$ , when the motion will remain steady. Hence such a machine should give induction currents of the greatest efficiency when used as a motor.

The above conclusions have been arrived at by considering the attractive and repulsive forces between different parts of a battery current, where the electro-motive force of the battery does not change.

#### MAGNETIC MACHINES.

The same reasoning will apply to the case where a permanent magnet is used in place of the original battery current, a closed circuit being moved in the magnetic field, or a magnet moved in the neighbourhood of a fixed coil. In fact, the theory of Ampère requires that a small closed current should be equivalent to a magnetic molecule, and so a collection of equal small closed currents, all going the same way, and occupying a given area, is equivalent to a collection of equal magnetic molecules with their poles in the same direction, i.e., to a magnet. But a collection of equal small closed currents all going the same way, and occupying a given area, is equivalent to a current around that area.

We may readily express the efficiency of magneto-electric machines by a formula. Taking  $k$  to be the effective work done by a unit current in one turn of the armature, and  $n$  the number of turns in a minute, and  $C$  the strength of the current, the total effective work is  $C^2 n k$ ; and the work done in overcoming the resistance,  $R$ , of the circuit is  $C^2 R \theta$  : hence, by Joule's and Ohm's laws, if  $E$  be the electro-motive force,

$$E C = C^2 n k + C^2 R.$$

$$\text{Hence the efficiency} = \frac{C^2 n k}{C^2 n k + C^2 R} = \frac{1}{1 + \frac{R}{n k}}$$

Thus, for a given resistance, the greater the number of turns of the machine, the greater is the efficiency, and the higher the resistance, the less the efficiency. This formula shows that machines and lamps of high resistance can only be efficient when the machines are revolving at a high speed.

We may represent the efficiency of batteries or

magnetic machines which are employed to drive an electro-motor, such as a dynamo-electric machine, by a diagram from *La Lumière Electrique*, in which the electro-motive force of the battery or exciting machine is measured on a horizontal line, and either the current or the energy expended is represented by vertical lines. The total electrical energy, represented by a straight line (III.), is the sum of the effective work (IV.), and the loss of energy by heating, &c. (VI.).

FIG. C.

- I. Electromotive force.
- II. Strength of current.
- III. Energy converted into electricity.
- IV. Effective work in the external circuit.
- V. The efficiency.
- VI. Energy not converted into useful work.

It will be seen that when the efficiency is  $\frac{1}{2}$ , the greatest amount of effective work is produced, and this amount of work is one-half the total electrical energy. Since the electro-motive force is proportional to the number of revolutions a minute, this diagram gives the effective work and efficiency at different speeds.

In the case where the fixed and the movable parts of the machine are electro-magnets, and the same current passes round both, then we have—

- (1.) The action of the currents on one another.
- (2.) The action of the fixed magnetic core on the moveable coil, and of the moveable magnetic core on the fixed coil.
- (3.) The action of the two magnetic cores on one another.

Hence the value of  $k$  is of the form  $a + bm + cm^2$ , where  $a$ ,  $b$ ,  $c$  are constants, and  $m$  depends on the magnetic properties of the cores.

Each of these actions arises from the influence of two equal currents on one another, and, therefore, will be proportional to the square of the current, and to the number of turns of the coil in a minute, so that—

$K$  is proportional to  $N^2 (a + bm + cm^2)$  and the efficiency—

$$\rho = \frac{1}{1 + \frac{c_1 R}{K}} = \frac{1}{1 + \frac{R}{N(a + bm + cm^2)}}.$$

The most important part of the action in such machines depends on the action of the two mag-

netic cores one upon another. The disturbance between the fixed and the moveable core, in consequence of the great disturbance, in consequence of the taking up their full magnetism in requiring time for their full magnetisation; sequence of this, in all dynamo-electric machines, is necessary to allow the rotation to go on an angle determined by the retardation of magnetism of the cores, before taking current from the machine to do external work, hence, in order to get the greatest efficiency, the springs for making contact must in some cases be shifted round in the direction in which the rotation is taking place. Faraday attributed the delay to the time required to develop the currents in the molecules of the magnetic

#### ALTERNATE-CURRENT MAGNETO-MACHINE

In alternate-current machines, there is a commutator for making the current continuous. The currents from the coil are collected through the external resistance in opposition for every half-turn of the arms. The earliest of these was the "Alliance" electric machine, which has been adopted by the French Government for lighthouse illumination. Mr. Holmes converted this into a continuous machine, and was the first to produce the electric light on a grand scale for illumination. He afterwards removed the commutator, and again converted it into an alternate-current machine.

The four methods of placing the coils on the revolving wheel, in machines for electric light, which have been employed in lighthouses, have been summed up by Mr. Douglass:—

1. In Holmes's magneto-electric machine, the bobbins are arranged transversely, with parallel to the axis of rotation around the circumference of the wheel.
2. In Siemens' machines, the wires are wound, and revolve about the long axis of the coil, on which they are wound.
3. In Gramme's machines, the wires are wound around a ring.
4. In the De Meritens machines, the coils are wound as in the Gramme, but are divided into separate parts, which are insulated from one another, and passing in succession to opposite poles of magnets, give off currents.

#### THE SIEMENS ALTERNATE-CURRENT MACHINE

A central disc carrying bobbins is mounted at angles to a shaft, and revolves between two electro-magnets ranged in circles on the shaft, having their axes parallel to the disc. The bobbins have no iron cores, and so the disturbance caused by magnetisation and demagnetisation of the iron is avoided. The electro-magnets are excited by a small Siemens continuous machine.

This is similar to Wilde's dynamo machine, which he produced in 1866, in which the coils on his cast-iron disc were wound with iron cores, and arranged them so as to have groups of four each. The current in these groups excites the electro-magnets, and the other seven groups give out the current for use. Among the more recent machines

es, arranged so as to be excited by a separate current machine, there is one which has been invented by M. Gramme, in which the of the continuous-current machine, which the magnets, is placed on the same axis as the rotating armature which gave the alternating currents, so that the two turn with the same speed, and the combined machines run at the same rate. This is much simpler than having two separate machines, and it is called a self-acting machine. The principles which I have already explained, the greatest amount of effective work or yield obtained from an alternate-current machine, driven by a separate exciter, is not more than 50 per cent. of the electrical work given out by the first machine.

#### RESULT OF M. MASCART AND M. JAMIN'S EXPERIMENTS.

Jamin has found that, in the Alliance machine for electric light and giving alternate current, the strength of current can be calculated by Ohm's law, considering the electro-motive force proportional to the velocity, but replacing the resistance of the bobbins by a resistance about ten times as great. The resistance to be added is proportional to the velocity of the machine. Theoretical determinations of the efficiency of machines are complicated by the retardation of the rotation of the magnets, which necessitates a change of position of the commutator in the course of the rotation of the armature. If this were not made, then it would be possible, in the machine in which the wire resistance was to get currents in opposite directions when it is rotated at different rates. For slow rotation, the galvanometer needle is deviated to the right; on increasing the velocity of rotation, the deflection is increased, at last reaches a maximum and beyond that diminishes rapidly to zero, and becomes negative; as the velocity is increased the current reaches its greatest negative value, and then increases again, and may have such fluctuations.

The efficiency of the Siemens dynamo-electric machine has been examined experimentally by Dr. W. Siemens, who has communicated the results of his investigations to the Royal Society. Dr. Hopkinson, whose results are published in the "Transactions of the Institution of Mechanical Engineers;" also M. Hospitalier and Dr. Auerbach and Meyer have experimented with similar machines, and M. Mascart and Angot considered the subject, both theoretically and experimentally, in some excellent papers which have been given in the "Journal de Physique." In the experiments of M. Hospitalier as published in *La Lumière Electrique*, we get the results shown in the diagram.

	Ohms.
Total resistance of the machine before the experiment, was	1.185
" of the heated bobbin	.75
" of the heated electro-magnet	.72
Total	1.47

Distances are laid down on the horizontal line on the scale of 1 c.m. per ohm.

Scale of electro-motive force (I.) is 1 c.m. for 10 volts.

The scale for currents (II.) is 1 c.m. for 10 webers. The scale for work (III. and IV.) is 1 c.m. for 20 kilogrammetres.

Curve (v.) represents the efficiency, i.e., the ratio of the effective work in the outer circuit to the total work converted into electricity.

This curve expresses the ratio of the external work to the total work produced, and approaches the value unity as the resistance is increased; but for high resistances very little work is produced.

FIG. D.

- I. Electromotive force.
- II. Strength of current.
- III. Energy converted into electricity.
- IV. Useful work in the external circuit.
- V. Efficiency.

From the curves it would appear that this Gramme machine does most effective work in the outer circuit, without greatly heating the internal circuit, when the total resistance is about 4 ohms, i.e., when the external resistance is about twice as great as the internal resistance. For less resistances the machine is greatly heated from the amount of internal work consumed, and for higher resistances the work converted into electricity becomes very small. The following numbers give the results of one experiment with the dynamo-machine:—

No. of turns a minute	1,000
External resistance	2.7 ohms
Current	25.5 webers
Electro-motive power	107 volts
Total work converted into electricity	3.64 h.p.
Effective work in external circuit	2.38 h.p.

The efficiency in this case is 65 per cent. The effective work in the outer circuit is not more than 50 per cent. of the total work done to produce it.

#### WITH GRAMME MACHINE.

In Auerbach and Meyer's experiments for 800 revolutions a minute, the maximum electro-motive force is 76 volts, and for 51 volts, or two-thirds of the maximum value, there is a current of 6.5 webers through a resistance of 7.8 ohms. Below this value the current is unsteady. With Siemens's machine, a speed of 700 revolutions a minute gave a maximum electro-motive force of 76 volts, and for 51 volts there is a current of 15 webers through a resistance of .6654 ohms. With

a small Siemens machine, a speed of 1,000 revolutions per minute gave a maximum electro-motive force of 42 volts, and for two-thirds of this, or 28 volts, the current was 11.2 webers through about 2.2 ohms resistance.

Dr. Hopkinson has investigated the way in which the electro-motive force in a Siemens machine depends on the current. He has shown that:—

- (1.) The electro-motive force is for a given current, proportional to the speed of revolution of the armature.
- (2.) That the electro-motive force does not increase indefinitely with increasing current, but,
- (3.) Only increases in the direct ratio as the current increases up to about two-thirds of its maximum value.

The current is very unstable for small changes of resistance, or of speed of engine, as long as the value of electro-motive force is less than two-thirds of its maximum value. There is a remarkable difference in the ratio  $\frac{E}{C}$ , depending on change of speed from 660 to 700 revolutions a minute, shown in Fig. 1, where the current changes from 5 to 15 webers, for this increase of one-tenth of the speed.

As regards the relation of work converted into electrical energy to the work expended to produce it, it appears from the experiments of Mr. Schwendler and Dr. Hopkinson that, with the Siemens machines employed by them, the loss of power was from 12 to 14 per cent., so that if the external resistance of the circuit, *i.e.*, the electric lamp, &c., be so adjusted that half the total work produced appears in the arc, then 43 or 44 per cent. of the total work expended is produced in the arc.

The results arrived at by Dr. Siemens with his latest machine on Wheatstone's principle are—(1.) That the electro-motive force, instead of diminishing with increased resistance, increases at first rapidly, and then more slowly towards an asymptote. (2.) That the current in the outer circuit is actually greater for a resistance of  $1\frac{1}{2}$  ohms than for one ohm.

With a current of 30 or 40 webers the horsepower expended was 2.44 h.p., and the effective work 1.29 h.p., giving an efficiency of 53 per cent., as compared with 45 per cent. in the ordinary Siemens machine. The maximum energy which can be converted into heat in the machine is 1.3 h.p. The new machine will give a steadier light with greater economy, and may be driven by a smaller engine.

#### THE BRUSH MACHINE.

Among the later continuous current machines are two which promise to be very successful machines. The Brush, with a ring on the Gramme system, with eight divisions or portions hollowed out to receive the coils, the bobbins at opposite ends of a diameter being connected together and to a commutator. When a pair of bobbins passes the neutral point, so that there is no current in it, it is put out of circuit for one-eighth of a revolution, so that the current produced in the other bobbins is not wasted, by being sent through the resistance of the two which are producing no current. On the inducing magnets are wound

fine wires, offering considerable resistance to carry the current when the external circuit is open, and keep up the magnetism; but when the circuit is closed, the thick wires on the armature carry the principal part of the current.

The internal resistance of the machine is about  $10\frac{1}{2}$  ohms, and the external resistance, there was, according to calculation, of 10 webers, and an electro-motive force of 839 volts. With these numbers, the work on the external circuit ought to be the whole electrical work produced; but actually, it is only 61 per cent.

The relation of work converted into electrical energy to the work expended in this machine, is 73 per cent., whereas with both Gramme and Siemens's machines, with relatively smaller resistances, this ratio is about 88 per cent.

Another continuous-current machine from Burgin machine from Switzerland, which has just been introduced into England by Mr. C.

FIG. E.—THE BÜRGIN MACHINE.

Four or six coils are wound on the square or hexagonal frame, consisting of iron. The corners of the frame come very near the poles of the magnets. There are six of these frames arranged successively in the form of a helix. The action is similar to that of the Gramme machine, the dynamo-electric principle being introduced in this as in other machines. The construction of the machine is very simple, and its efficiency has been proved by M. du Moncel and Mr. Crompton to be remarkably good. These machines are of small internal resistance, and are adapted for high speeds (up to 1,600 revolutions a minute), so that there is considerable electro-motive force.

The efficiency of certain Gramme machines

by Mr. Crompton, and tested at the Electric Light Exhibition, was shown to that, with a power of 4 h.p. expended in the current, only  $\frac{1}{2}$  h.p. was expended on and passive resistances, so that about 88% was nett power. This  $3\frac{1}{2}$  h.p. converted electricity gave a current of 32 webers through a resistance of about 2 ohms, i.e., an internal resistance of 1.077 ohms, and the arc of a Crompton giving a light equivalent to 2,158

we may compare with these the results obtained by Mr. Crompton for the Bürgin machine, at a speed of 1,675 revolutions per

min. machines were tested, and the total work expended was 5.45 h.p. The amount spent on and passive resistances, when the circuit was about .25 h.p., so that about 86% is nett power. The work converted into electrical energy, 5.2 h.p., gave a current of 20.15, through an internal resistance and connecting wires of 2.8 ohms, together with the arc Crompton lamps (about 5 ohms), each giving a light of 2,103 candles, measured horizontally; the motive force =  $\frac{\text{work}}{\text{current}}$  being equivalent current volts.

photometric measurements made horizontally, the electric light being level with the arc, the carbons being concentrically adjusted, the length of the arc being about 3 m.m., the amount of light was found to be obtained at 5 revolutions per minute, with 3 lamps, of 2,103 candles, or with 4 lamps, each of 2,103 candles. The upper carbon was 10 m.m., the negative carbon 13 m.m. in thickness. Consumption of the upper carbon was 4 c.m., the lower nearly 2 c.m. per hour. The total power expended was 5.55 h.p., and the light, with 3 lamps, varied from 18.36 to 21.94, and with 4 lamps, from 16.9 to 19.6. All three lights were very steady, and whiter than the single lights of Gramme's arc.

Mr. Crompton has been kind enough to lend me, for evening, a new Bürgin machine, about which I ask you the following facts:—It was tried at 1,675 revolutions a minute, and a current of 28 webers was sent by it through 3 lamps, in series. The arcs were lengthened to one-fourth of an inch each, the current was 24 webers, and the light was 5,000 candles each, the photometric measurements being made in the most favourable direction.

The British Electric Light Company have been good enough to place at my disposal for this evening for my lecture next week, two Gramme machines for trying some of the electric lamps have been kindly lent to me.

These machines are driven by a steam-engine, by Messrs. Robey, of Lincoln, and for the arc and other electric lamps I am indebted to the British Electric Light Company; to Messrs. Siemens; to Mr. Crompton; to Mr. Latimer Clark for the Lontin lamp; for the Rapieff and electric candle, to Mr. Berly; to the Jabach Electric Light Company for their candles; to the Anglo-American Electric Light Company for the Brush lamp.

### THE BROOKIE LAMP.

The upper carbon is attached to an iron tube, which passes into a solenoid, through which it passes as the positive carbon burns away. The solenoid forms a shunt or by-pass for the arc, and takes a small part of the current, and holds up the iron tube which carries the upper carbon; as more current passes through the coils, the motion of the carbon is stopped.

A commutator is so arranged and driven by the dynamo-machine as to break the current, and allow the carbons to come in contact for an instant at regular intervals, say every minute. Then the circuit is completed again, the upper carbon is drawn to its proper distance apart, and the light continues. At every minute the light goes out, but instantly relights, and no variation of light is perceived.

### SIEMENS' DIFFERENTIAL LAMP.

FIG. F.—SIEMENS' DIFFERENTIAL LAMP.

A thick wire bobbin, T, carries the arc current, and another fine wire bobbin, R, forms a shunt to the arc. The interval between the bobbins equals the height of each of them. The iron rod, SS, is of twice the length of each bobbin, and its ends in the normal position are at the centres of the bobbins. The attraction by the thick wire bobbin tends to lengthen the arc and diminish the current, and so its attraction is weakened, and the arc is again diminished, the attraction on the iron being regulated by the change of resistance in the arc. A pendulum arrangement is attached, to prevent the oscillations of the carbon from being too sudden.

### CROMPTON LAMP.

The carbons are brought together by means of the weight of the upper carbon holder, as in the Serrin lamps. The carbons are controlled by means of an electro-magnet, of which the principal armature separates the carbons, and a light secondary armature is arranged on the back of the large one, and does the more delicate work of bringing the carbons together. The large armature supports the negative or lower carbon; and when the small armature has brought the carbons together, so that a current passes, the large armature separates them to the proper distance apart for a good light. When the arc is broken, the armature, supported by a spring, is raised, and brings the carbons into

contact, and re-lights the lamp. The small variations in the strength of current re-act on the second armature, which is held at some distance above the large armature by a light spiral spring. The small armature carries an arm, which is applied as a brake to a brake-wheel, which is the last wheel of a train of wheels, set in motion by the weight of the positive carbon-rod.

#### REGULATOR IN BRUSH SYSTEM.

A very pretty arrangement for shunting the current past a lamp (when it is not in use), so that one lamp may be put out without affecting the other lamps in the circuit, is adopted on the Brush system.

The current passes through a solenoid coil, wound with thick wire, and then passes to the upper carbon, through the arc to the lower carbon, and then by the frame to the next lamp. The solenoid holds up a rod of iron, which tilts a ring on one side, through which the carbon passes, and so locks it. To the end of a thick wire of the solenoid is attached a thin wire (150 ohms), which is also wound on the solenoid, and which forms a shunt or by-pass to the arc, taking more and more of the current as the resistance of the arc increases. This thin wire is wound the opposite way, and the current in it relaxes the hold on the carbon, so that it falls slowly, and then takes more of the current. As soon as it does so, it is again held fast. To prevent the carbon from falling too rapidly, it is passed through a vessel containing glycerine, and slides downwards very slowly. The current through the thin wire also passes through another solenoid, which forms a shunt or by-pass to the whole lamp, so as to take all the current past the lamp if it should get out of order. When a considerable current flows by this path—i.e., if the arc becomes an inch long, so that its resistance is greatly increased—the second solenoid draws up a piece of iron, which lets all the current pass and the lamp is thrown out of the circuit.

In the Brush lamp, which is designed to burn 16 hours, there are two pairs of carbons, with the rings on the upper carbons, which hold them by friction, so adjusted that one is held about one-fourth of an inch above the other, and, therefore, the second carbon will not come into action until the first falls or is burnt out.

All the electric candles, such as the Jablochkoff candle, the Jamin candle, the Wilde candle, and the De Meritens candle, consisting of three carbons, are fed by means of alternate current machines, because it is essential that the two carbons should burn away equally. In the Jamin and the Wilde candle the carbons are at first in contact, but when the current passes, one of the carbons is separated from the other, because its holder is set on a hinge, so as to be acted upon by a small electro-magnet through which the current passes.

M. Joubert has found that it is necessary, in order to keep the arc steady with the Jablochkoff candle, that the alternate current in the circuit should have a mean value of eight or nine webers, and that below five webers the arc cannot be kept alight; between the bases of the two carbons forming the candle there is an electro-motive force of 40 or 45 volts. The Jablochkoff candle uses up about 66 kilogrammetres of work,

of which 33 kilogrammetres, or 4.6 h.p. is converted into heat and light.

When the arc is produced in a magnet either by disturbing it by an electro-magnet by placing a frame around it, as in the candle, it is necessary to have a current large again as when the electro-magnet is in action. One-third of the energy of the current in such a case is spent in producing a strong magnetic field around the electric arc, and is, therefore, much wasted energy, as far as the electrician is concerned.

## MISCELLANEOUS.

### THE SYMPATHETIC TELEGRAPH

The following article on the curious and relating to a sympathetic telegraph is taken from *Antiquary*:—

Of sympathy, or some comat'ral force,  
Powerful at greatest distance to write,  
With secret amity, things of like kind,  
By secretest conveyance.

So wrote Milton, and so have thought many more particularly the famous but credulous Sir Digby, who, in 1657, delivered a discourse, entitled, "Touching the Cure of Wounds by the use of Sympathy," which was afterwards translated into English by R. White, and who is said to have cured Howell the letter-writer's cut by the use of the powder at a considerable distance from the wound. When the mariner's compass, as generally known, as it was apparently in the 15th century, the supposed wonders of magnetism have attracted the attention of imaginative Alexander Neckam, monk of St. Alban's (he died 1217), has the credit of being the first European writer to allude to the compass, evidently the remarkable movements of the needle first induced dreamy philosophers to believe sympathetic telegraph was a possibility. One of the first inducements, which Addison contributed to the *Spectator*, "of a chimerical correspondence between friends by the help of a certain loadstone, and such virtue in it that if it touched two several needles when one of the needles so touched began to move, though at never so great a distance, move at the same time and in the manner." This is the origin of Strada's "Prolusions," but earlier writers have to the supposed phenomenon, and Mr. Latta has collected a curious series of books on the subject, which he has sent to be at the Paris Electrical Exhibition.\* The first description of the sympathetic telegraph, which he did in 1558 in his "Natura Hebraica," He is said to have derived the idea from Cardano Bembo (1470-1547), but the observations of the celebrated historian and poet on the subject have been traced.

Daniel Schwenter, of Nuremberg, who wrote under the assumed name of Jacobus Hieronymus de Saxa the next (in 1600) to allude to the supposed sympathetic telegraph. He described how attention was drawn by the use of bells by means of bar magnets, and how the words were formed by one, two, or three strokes to the right or left. His ideas were purely cabalistic, but his description singularly coincides with some of the

\* Mr. Clark has kindly supplied the writer with a list of books, made by Mr. Frost, Librarian of the Society of Engineers, from which, with some references to the *Antiquary*, this article has been drawn up.

an telegraph. B. de Boot, the author of the *eweller*," drew attention to the telegraph in then in the year 1617, Famianus Strada is "Prolusions Academicæ." In this book printed those verses describing the imaginary graph, which were written in imitation of and have themselves been constantly transcribed by later writers. One of these was George Hakewill, D.D., Archdeacon of Surrey, a curious book full of the learning of his, he entitled, "An Apologie or Declaration of Providence of God in the Government of the World." It is a folio volume, printed in London, Allott, in the year 1630. The fourth section of the book is, "Of the Use and Invention of the Compasse or Sea Card, as also of another invention, said to be lately found out upon the sea;" and this section contains a versified description of Strada, of which, as it is less known, I give here in preference to the original.

you of ought would faine advise your friend  
far off, to whom no letter you can send,  
th round table make, write down the Christcrosse

he verge thereof, and then bestow  
in the mid'st which touch't the load, that so  
when you lift it straight may turne unto;  
another orbe, in all respects like this,  
edge, and lay the steels thereon likewise,  
rich from the self-same Magnes motion drew;  
aid with thy friend what time he bids adieu;  
aye, agree first when you mean to prove  
stirred and to what letter it doth move  
with thy friend thou closely would advise,  
entry off furr distant from the lies,  
the orbe and steels which on the orbe was set,  
cease on the edge thou see'st in order writ,  
will frame thy words to them direct thy steels,  
times to this, sometimes to that note wheele,  
and about so often till you finde  
impounded all the meaning of your minde.  
that dwells far off, O strange! doth plainly see  
stirre, though it by no man stirred bee,  
where, now there, he conscious of the plot,  
guides, pursues and reads from note to note;  
ing into words those notes, he clearly sees,  
ful to be done, the needle truchman [interpreter] is,  
in steels doth cease its motion, if thy friend  
venient answer back to send,  
urse he may take, and with his needle write.  
e severall notes what so he list indite.

fewell then goes on to refer to the Annotationer upon T. Livius, and as he conveys refers to his authorities, he tells us that, on a column of his first volume, that author says: "The letter might be read through a stone wall of three e, by guiding and moving the needle of a over the letters of the alphabet written in the stone; but the certainty of this conclusion I have experiment of such as list to make tryall of

as before Dr. Hakewill's "Apology" apicholas Cabeus published his "Philosophia," and in that work he gave the first picture graph. It merely showed a round dial with a "se" alphabet all round its outer edge, and a needle loosely attached at the centre. Robert is the first English writer to represent this this he did in his translation of "Ars he Notary Art of Solomon" (1657). His figure to that of Cabeus, with this exception, uses an alphabet of capitals in place of small letters. He describes the pure steel like that used in seamen's compasses, but of gnuited, so that after being touched by the load may be cut in two, when each needle must be in a separate box. In one of Bishop Wilkins's books, "Mercury, or the Secret and Swift : showing how a man may, with privacy and uncommunicate his thoughts to a friend at any (1641), the author alludes to the sympathetic although he does not believe in its virtues. In the seventh chapter is "of those common relations

that concerne secret and swift information by the species of sight which are either fabulous or magical," and here he writes, "first of those that are fabulous. In which kind, that of the loadstone is most remarkable, as it is maintained by Famianus Strada in his imitation of Lucretius his stile and divers others."

Besides the authors already referred to, there are a large number of others who either describe the instrument or make a passing allusion to it. Of these the most prominent are H. Van Etten (1624), Pancirollus (1629), A. Kircher (1631), Galileo (1632), Sir Thomas Brown (1646), J. Glanvill (1661), Wymant van Westen (1663), Gaspar Schott (1665), W. E. Heidel (1676), L. H. Hillier (1682), De Lanis (1684), and De Vallemont (1696). It is a singular instance of the way in which we copy one from another, that so many writers should have made mention of this purely mythical instrument, some of them apparently with undoubting faith in its virtues.

In an indirect manner, the name of an eminent statesman is connected with this famous dial. Cardinal Richelieu had private agents in many countries, who kept him so well informed with news, that those who knew nothing of the agents thought it necessary to find some explanation of his early knowledge of events, which seemed to them almost like a prophetic power; so they gave out that Richelieu possessed a sympathetic telegraph. The wily Cardinal blandly denied the rumour with smiles, and was not sorry that those around him should be thrown off the right scent.

Some persons believed that the dial might be made with human flesh. A piece of flesh was cut from the arms of two persons, and, while still warm and bleeding, was mutually transplanted. The severed piece grew to the new arm, but retained its sympathy with the old, so that the former possessor was sensible of any injury that it underwent. When the flesh had grown to the new arms, letters were tattooed upon the transplanted pieces; and on one of the letters of one being pricked with a magnetic needle, the friend at a distance immediately felt a sympathetic pain on the same letter on his arm. This reminds one of Taliacottus and his remarkable operations, which inspired Edmund About to write his curious novel, "Le Nez d'un Notaire," in which he relates the odd results of sympathy between the notary's nose and the arm of the man from whom the flesh was taken.

Allusion has already been made to Addison's remarks in the *Spectator* (No. 241) upon Strada's account, and it is worth mention, as a curiosity of literature, that the celebrated essayist actually repeated his remarks word for word in the *Guardian* (No. 119). One of the latest translations of Strada's verses will be found in an Oxford magazine entitled "The Student," which opens thus:

With magic virtues fraught, of sov'reign use,  
Magnaesia's mines a wondrous stone produce.

Although the telegraph, about which we have been writing, was purely sympathetic, and no provision was made for a connecting wire, yet some may consider it a curious prevision of what has since been successfully carried out. The dial certainly does appear to have borne a singular likeness to a Wheatstone A B C telegraph. The Rev. Joseph Glanvill looked forward in Charles II's reign to the time when communication of this character would be general. That singular man wrote as follows, in a work addressed to the Royal Society:—

"I doubt not but that posterity will find many things that now are but rumours verified into practical realities. . . . To those who come after it may be as ordinary to buy a pair of wings to fly into the remotest regions as now a pair of boots to ride a journey, and to confer at the distance of the Indies by sympathetic conveyances may be as usual to future times as to us in literary correspondence."

LESSONS IN THE HIGHEST AND THE HUMBLEST BRANCHES OF THE ART WOULD BE GIVEN. As West Herts has no towns large enough to support a permanent school, the school of cookery would not remain in one town, but would pass, with its staff and *batterie de cuisine*, through the leading towns of West Herts—Watford, St. Alban's, Berkhamstead, Hitchin, &c., staying about six months in each town, and returning to its former stations every three or four years. To reach the elementary schools arrangements would be made in each town for training teachers specially prepared in the system which has been for several years successfully carried out at Watford-heath, Berkhamstead, and Bushey. Apprentices of about 17 years would be regularly bound to the association for [three] years, paying an apprenticeship fee of about £10, to protect the association from possible loss on training. Their pay would be [£15] for the first year, [£30] for the second year, and [£45] for the third year, with power on the part of the association to cancel the engagement at any time. After about six months' training, the apprentice would be sent out to teach in elementary schools desirous of having lessons. No charge would be made to the schools for these lessons. The only expenses falling upon the schools would be the cost of furnishing, and of any loss on food, which at the outside should not amount to more than £5 a year. It is probable the Education Department will extend to England the grant of 5s. a head now made in Ireland for cookery. The association might fairly stipulate for a part or the whole of this grant. An apprentice would be able to teach five schools, at an average cost to the association of £6 a year for each school. If managers should prefer to train their own pupil-teachers specially to this work, arrangements would be made to meet their views. As the central school moved through the principal towns of West Herts, it would, it is hoped, supply the wants of the schools by one or other of these means. Cookery is at present taught in the schools of the large towns of England; it is the country schools which are generally deficient in this teaching. By this plan of combination, it is thought that the difficulties which now deter country managers may be overcome. Those who are acquainted with the condition of the poor, as regards cookery, will doubtless sympathise with an effort to impart to them information as to the value of many foods

finish their arrangements. The principal entrance is the main north pavilion, facing the river. The eastern entrance is occupied by the railway, by which visitors paying no admission can visit the building. The other entrance is on the Place de la Concorde.

The great hall of the Exhibition building, 250 metres in length by 100 in width. Lofty iron pillars support an arched roof of glass; they are 8 metres apart, the spaces under which contain boilers, and dynamical apparatus. Belleville boilers, which are heated by 16,000 lb. of steam per hour, or a 100 h.p. nominal. There are also Otto engines, of 200 h.p. more. This is supplied by the French syndicate, which supplies for a charge of 33 per cent. on the French, English, and Belgian manufactures many more steam-engines for use by private contract.

An interesting collection of his apparatus arranged by Mr. H. R. K. by the Postmaster-General. Here is a five-needle instrument constructed in 1837, and specimens of the development of the instrument, from the complicated simplified one-needle instrument, large in local circuits, and on railways; showing similar development, from the olden days of electricity to the designs by Varley and Spagnoletti for the underground telegraph, as Hammer-smith as long ago as 1816. This is the first A.B.C. instrument constructed by him in 1840. This is the weak apparatus, and may be compared with the instrument, as constructed in 1848, as used by the old Magnetic Telegraph. A specimen of the first submarine cable in 1850, is exhibited, as is Varley's which was long used at the Central Commission and distribution of time-signals. It is announced that the Technical Exhibition are about to organise a series of lectures on some of the inventions exhibited will not be open to the public.

## AL OF THE SOCIETY OF ARTS.

No. 1,502. Vol. XXIX.

NDAY, SEPTEMBER 2, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## ART FURNITURE EXHIBITION.

Exhibition of Works of Art Applied to  
re, in connection with the Exhibition of  
s at the Royal Albert Hall, is now open  
A non-transferable season ticket will be  
any member of the Society on application  
secretary.

## MEETINGS OF THE SOCIETY.

## CANTOR LECTURES.

SCIENTIFIC PRINCIPLES INVOLVED  
IN ELECTRIC LIGHTING.

Professor W. Grylls Adams, F.R.S.

z IV.—DELIVERED MONDAY, MARCH 28,  
1881.

*Effects of the electric current.—Incandescent  
—Luminous effects of electric currents in a  
n, and in various gases.*

gas was first introduced extensively for  
purposes, many objections were raised to  
and among them was one which was  
l by Clement Desormes, in 1819, which is  
up in the following quotation :—

light is of a disagreeable yellow colour, entirely  
from that red and warm gleam of oil lamps;  
dazzling brightness; its distribution will be  
le and irregular, and it will be much dearer  
lighting, and, even if it should be improved,  
ill remain much dearer than those lights which  
ly possess."

as Desormes had become accustomed to the  
sm of oil lamps, and objected to the cold-  
the yellow gaslight, so, a year or two ago,  
r objection was raised against the electric  
at it was entirely different from the yellow  
rm gleam of gaslight; that it is of a  
; brightness; that its distribution would be  
le and irregular; and that our streets  
e left in darkness.

objections do not seem to be so strongly  
p by the public as they were two years  
f they have seen several trials of the

electric light; and, although there are many diffi-  
culties in the way, yet the fact that the electric  
lighthas all the colours more uniformly blended,  
and is, therefore, a whiter light than gas, and  
enables objects to be seen in their true colours,  
can hardly be urged any longer as an argument  
against its use. The same argument might be  
urged for the same reason against bright moon-  
light, or against the light of day, and in favour  
of a yellow London fog. The Kyrle Society, in  
its search after truth and beauty, must surely be  
strong supporters of the spread of the electric  
light.

If we turn to the Report of the House of Com-  
mons, we find the following statement :—

"A remarkable feature of the electric light is that it  
produces a transformation of energy in a singularly  
complete manner. Thus the energy of 1-horse power  
may be converted into gaslight, and yield a luminosity  
equal to 12-candle power. But the same amount of  
energy transformed into electric light produces 1,600-  
candle power."

The experiments of Mr. Schwendler, of Dr.  
Hopkinson, and of others, have shown that, both  
with the Siemens machine and with the Gramme  
machine, 88 per cent. of the total work expended  
is converted into electrical energy. Theory has  
established that, if the external resistance of the  
circuit is equal to the internal resistance of the  
battery or magneto-machine, the available work  
in the external circuit is a maximum.

Suppose, then, that we have 40 Grove's cells,  
each of .25 ohms resistance, and of an electro-  
motive force of 2 volts, the external resistance  
being 10 ohms—

$$\text{Then } Q = \frac{E}{R+r} = \frac{40 E}{40 \times .25 + 10} = 4 \text{ webers,}$$

$$\text{And } EQ = 2 \times 4 \times 40 = 320.$$

The work done in the external circuit is  $\frac{320}{9.81 \times 2}$   
= 16 kilogrammetres per second nearly, or about  
 $\frac{1}{2}$  h.p.

A small Gramme machine of the A type,  
having an internal resistance of 4.58 ohms, and  
with an external resistance of 4 ohms, gives an  
electric current of 17.5 webers and an electro-  
motive force of 158.5 volts, giving an amount of  
work equivalent to 2 h.p.,  $EQ = 160 \times 17$   
nearly = 8 times the energy of 40 cells of Grove.

If we wished to replace such a machine by  
Grove's cells, we should have to arrange about 80  
cells to get the same electro-motive force, and to  
make each cell about four times as large, or to  
arrange 320 cells in four sets of 80 in each set,  
to get the same amount of external work done as by  
the Gramme machine. This will show how im-  
possible it is to do the work by voltaic batteries  
which can be done by magneto-electric machines.

The equation, work = EQ, may be satisfied in  
two ways—either by making Q large and E small,  
i.e., making what is called a quantity machine  
which will only do effective work when the  
external resistance is small; or we may make Q  
small and E large, i.e., what is called a tension  
machine, which requires an external resistance  
large enough to prevent the machine from being  
overheated, and to satisfy the relation for the  
greatest amount of external effective work.

small resistance, and in the other a smaller current is sent through nearly four times the resistance, and to do this a higher electro-motive force is required. This higher electro-motive force is obtained by increasing the number of turns of wire in the bobbin and in the magnet, so strengthening the magnetic field, and also by increasing the number of turns of the machine.

We arrive, then, at the conclusion that, to overcome higher resistances more effectively, higher electro-motive force, and therefore higher speed, is required. Now our resistances may be so high that an ordinary current of electricity, even from a dynamo-machine, will not pass through it, in which case we have to resort to another method of producing electricity, of still higher electro-motive force, but the quantity produced is then considerably diminished. We have then to take an induction coil, consisting of two coils, in one of which a current of electricity from a battery is passing, and by suddenly breaking and making this current, to obtain great changes of the magnetic field, and hence great electro-motive forces, and so get very powerful alternating currents. We know the effect of checking suddenly the flow of water in a pipe. Sometimes the increase of pressure so produced may be sufficient to burst the pipe, and this is one transformation of the energy of motion of the water. This is analogous to the development of the energy of the induction current by the sudden checking of the electric current in the primary circuit. Water may be raised to a high level by a series of sudden impulses, as in the hydraulic ram. A flow of a considerable quantity of water being suddenly stopped, there is at once a sudden increase of pressure, which is sufficient to lift a valve, and allow a small quantity of water to pass into the reservoir or air-chamber. This air-chamber regulates the action of the flow of water up the pipe from the reservoir, just as the resistance and capacity of the secondary circuit regulate the

kindly lent to me by Mr. Lat these Joel lamps kindly lent who has introduced several the original Werdermann lam the contact of carbon is very an ohm; hence it will take 7 or 8 (or perhaps 10), arrang same circuit, to equal the resist arc. To work these lamps of a low electro-motive force is a result is attained by driving dynamo-electric machine at m or by placing a considerable s series, so as to make their c equal to or greater than the in the machine. Thus a Gramme at the rate of 1,200 revolutio an electro-motive force of at give a current of 50 webers lamps in series. But this illumination of 320 candles in with this current we get an il candles in 10 lights. Now, th to produce this rate of revol machine, is about 9 or 10 Werdermann, or the Joel lamp lights of 160 candles each for expended.

Mr. Alex. Siemens lays down "Electric Lighting," that 4 l 15s. a ton, will produce 1 h.p. and that, if a steam-engine be an electric light of 6,000-cas would be 5d. per hour. If th be produced by 15 lights of 4 cost would be 2s. 1d., or five tir the cost for a 400-candle lig rate of about 1½d. per hour.

Now, by comparison, we m the price of the electric ligh means of the Werdermann or compare the light obtained by

he photometer on the same level so that the surface is illuminated seeding horizontally from the lamp. nps, whether Werdermann or arc e fed by a continuous-current mant passes from the positive carbon always in the same direction; and , the upper positive carbon becomes a hollow; hence a portion of this s the light, and the greatest in- is not in a horizontal direction, at an angle of about 60° below The illumination in this direction is es—or even more than three times ion in the same horizontal plane ence, when it is said, in the report tests, that a dynamo-machine, at s per minute, will give a light of or an expenditure of 4 h.p.—the sured horizontally—we see that the a direction inclined downwards at 0° below the horizon, would be or 4 h.p. or at least 1,625 candles will also explain why lights fed -current machines should be placed le height above the area to be his, combined with the fact that it omical to produce one very powerful of a large machine, than several o illuminate the same area to the ill explain why Dr. Siemens is ge lamps at so great a height, for etric lights which we shall shortly unity of seeing in the City.

#### ON OF THE ELECTRIC CURRENT.

t to which I propose to draw your evening is the sub-division of the

plest to regard first the case where ery of given electro-motive force. ording to Ohm's law,

$$E = C(R + r),$$

electro-motive force,  $C$  the current, of the battery, and  $r$  the external he poles of the battery be joined resistances  $r_1$  and  $r_2$ ,

$$E = C \left( R + \frac{r_1 r_2}{r_1 + r_2} \right).$$

e of each branch is equal to  $r$ , and ent in each,

$$C(R + r) = 2C_1 \left( R + \frac{r}{2} \right).$$

ts,  $R = 1$  ohm, and  $r = 100$  ohms,  $= C(1 + 100) = 101C$ ,

$$= 2C \quad 1 + 50 = 102C_1.$$

asam current flows in each branch s on y one wire. If there are 10 l o 2 branches, and if  $C_x$  be the

$$C(1 + 10) = 110C_x,$$

n each branch is  $\frac{100}{110}$  instead of  $\frac{100}{102}$  ranches, and  $C_y$  be the current in

$$) = C_y(1 + 2) = 150C_y,$$

thus the current in each is  $\frac{100}{150}$  or  $\frac{2}{3}$ , and the heating or glowing effect is  $\frac{4}{9}$ ths of its value with only one branch.

Now, if with 50 branches in multiple arc, we diminish the external resistance of each branch so as to get the same current as at first through each branch,

$$\text{Then } E = C(R + r) \text{ at first,}$$

$$\text{And } E = 50C \left( R + \frac{r_1}{50} \right) \text{ with 50 branches.}$$

$$\text{So that } (R + r) = 50R + r_1,$$

$$\text{Or } r - r_1 = 49R.$$

Hence with  $R = 1$  and  $r = 100$  ohms  $r - r_1 = 49$  and the length left has a resistance of 51 ohms. The heating of each of these is  $\frac{51}{100}$ , or one-half of what

it was with only one branch. Hence the glowing heat or light from such a resistance will be greater than from the unshortened wire, with the weaker current through it. In this case we get 50 circuits of 51 ohms each, so arranged that the heating effect in each circuit is  $\frac{51}{100}$ , or about one-half of what it was at first. Hence the amount of heat radiated from each is one-half of what it was at first. But there are 50 such circuits, therefore the total heat radiated is 25 times as much as it was with only one branch.

If the resistance of the battery and connecting wires is considerable, then we see that the addition of every additional branch circuit takes away greatly from the amount of heat radiated from each branch, so that this plan of sub-division by separate circuits can only be adopted with success when the internal resistance is small as compared with the external resistance. We see, then, that with small internal resistance, there is great gain in heating, and, therefore, in light-giving power, by arranging branch parallel circuits in multiple arc; but when the resistance of the battery and leading wires is considerable, the advantage of this arrangement is small, and very little sub-division is admissible.

#### INCANDESCENT LAMPS.

Now, let us consider the case of currents produced by means of dynamo-electric machines, in which the electro-motive force is not constant in the same machine for the same speed, but depends upon the resistance of the circuit. An electro-motive force of 100 volts produces a current of one weber through a resistance of 100 ohms, and Mr. Swan tells us that this current, through a lamp of that resistance, gives a 60-candle power light. Now, if we reduce the length of the carbon filament in the lamp without altering the current, we reduce the illuminating power in the same ratio. Suppose we take it as four-fifths of the length, i.e., its resistance is then 80 ohms, and we shall get a 48-candle power light from the same current (one weber), i.e., with an electro-motive force of 80 volts.

With two such lamps in series, we shall get two 48-candle power lights, with an electro-motive force of 160 volts, sending a current of one weber through them, i.e., the two lamps should give out a light of six gas-burners of 16-candle power each,

and should be sufficient to illuminate a drawing-room in many of our London houses.

If we consider now how we are to produce this current, we find that a Bûrger machine, by the expenditure of 6 h.p., will send a current of 24 webers through an external resistance of about 7 ohms, giving an electro-motive force of 160 volts. If then we take two lamps in series, i.e., 160 ohms, and arrange 24 distinct series, we shall get a combined resistance of  $\frac{160}{24}$ , or about 7 ohms, allowing for the resistance of connecting wires, and there will be a current of 1 weber through each circuit, i.e., this machine should give us 48 lights each of 48-candle power. With a resistance of 50 ohms in each lamp, the number of lamps which may be supplied from the same machine will be double this number. If we reduce our electro-motive force from 100 volts to 80 volts, with the same length of carbon in the lamp, then we reduce the current from 1 weber to 8-10ths of a weber. This in the same resistance will reduce the illuminating power from 60 candles to a light of about 40-candle power, instead of a light of 48-candle power. Hence, with a given electro-motive force, more light is obtained, and, therefore, greater economy is affected by shortening the length of the carbon in the lamp, rather than by diminishing the current through the same length of carbon. Hence, the best results will be obtained in incandescent lamps by sending through them as strong a current as they will safely stand, and making the length of carbon such that the dynamo-machine employed will send such a current through them.

Take another case:—Suppose we have one lamp of 75 ohms resistance (i.e., about 45-candle power). A Gramme machine or a Siemens's medium-sized machine will give an electro-motive force of 100 volts, and a current of about 25 webers, at the rate of 100 revolutions a minute, through an external resistance of about 3 ohms. Hence, if we have 25 lamps in separate branch circuits, or in multiple arc, we get 1 weber through each from such a machine, and get a light, according to Mr. Swan, of 45-candle power from each. Hence, such a machine will give us about 1,125-candle power illumination. The energy expended would be about 5 or 6 h.p., so that the illumination would be about 200 candles per h.p.

We have seen above that, with the Siemens's alternate current machine, a 400-candle light requires about half a horse power; so that 1 h.p. will supply two lights of 400 candle power, from an alternate current machine, at the rate of 10d. for 3 hours. The same illumination can be obtained from gas, at 2s. for 3 hours. Now, two-thirds of this cost is for the supply of carbon, which becomes burnt in the arc. Hence, without this consumption of carbon, the expense per h.p. is only 10-9ths of 1d. per hour. Applying this to the case of incandescent lamps, in which our carbons do not wear out, we see that by a proper arrangement of the lamps we may get a 200-candle power light at the rate of 10-9ths of 1d. per hour.

Now, Mr. Alex. Siemens also states, in his paper, that at the rate of 3s. 6d. per 1,000 feet, the same illumination cannot be obtained from gas at less than 2d. per hour. Hence, allowing 8-9ths of 1d. an hour for the breakage of incandescent lamps,

the cost of light by gas and electric lamps would be nearly the same.

If we allow that only a light of 4 instead of 60-candle power, can be, at rate, still the incandescent light can be as an expensive light.

Now, in the absence of any actual system as in the Siemens or the Gramme. In the Brush system a current of 1 through an internal resistance of 1 external resistance of 70 ohms Siemens machine, when the external is seven times the internal resistance only 1-60th part of its value when internal resistances are equal, and 1 when the external is double the internal. The drawback to this arrangement is that one-third of the total work is lost in heating the machine.

Taking the Brush machine as we have the difference of potential for each circuit is about 40 volts. Hence of potential of 16 lamps = about 160. With an external resistance of 10 ohms is a current of 10 webers. Hence incandescent lamps in 10 series a resistance of 70 ohms, we shall get through each series. Put, then, of 100 ohms resistance, in each shall get 70 lamps from a Brush machine. 70 lamps are each of 60-candle power are worked by an expenditure of 10 h.p. the candle power is 4,200 candle power or 262.5 candle power per h.p. this resistance are only heated, light of 30-candle power each, power per h.p. will have to be reduced to 10.

Thus we have seen that it is to divide the electric current in such a way to increase the amount of illumination may be obtained by means of a machine, especially when the light is given by the incandescent system of Edison.

The earliest attempt to produce incandescence in a vacuum was made in 1843, who applied continuous conductors, and heated them in a Torricellian vacuum. In 1848 by Staite, who used an iron and platinum wire, and enveloped in glass or some other non-conductor. Konn employed graphite, and was incandescent in an atmosphere of hydrogen. There was no wasting away of the same principles have been applied with greater promise of success in attempts at producing incandescence. The earliest attempts (1) because of the impossibility of the consumption of the carbon in consequence of the material it was impossible to get of exhaustion which was because of the presence of hydrogen, which exists in other substances. It is our power of obtaining light greatly extended, and as

in vacuo from the labours of Mr. Crookes, Swan and Mr. Lane-Fox have succeeded in drawing vacuum from which all the air and hydrogen are exhausted, so that their filaments and platinum wire connections without being destroyed, even when a current of electricity strong enough to make them glow, a brilliant incandescent light has been steadily passing through them for months.

Through the kindness of Mr. Swan, my friend and former pupil, Mr. Lane-Fox, I was able to show you this evening how well they succeeded in producing a brilliant, and yet a steady and pleasant, incandescent light. This is a result which many have sought in vain, and which could not have been attained except by bringing together the results of investigations which have been recently carried on in several branches of physics.

I cannot conclude this course of lectures without my especial thanks to Mr. H. Trueman, who has given me very valuable assistance, and to me to bring together a large collection of electrical apparatus, in illustration of the subject which I have had the honour to present before you.

## MISCELLANEOUS.

### AGRICULTURE IN TRAVANCORE.

Agriculture is here carried on, says *The Colonist* and with some measure of practical skill and success from lengthened experience, but with most primitive implements, and needing much improvement as to the rotation of crops, and the preparation of the soil for the market. The principal native agricultural products are rice, cocoa-nut and other palms, and some roots for food, besides coffee, which is cultivated by European planters, with the aid of native labour.

Fruit trees also are grown, more or less, by the natives, and invariably planted at the beginning of the year when waste land is cleared.

#### RICE.

Rice is grown chiefly on irrigated or swamp land, dry or "hill" rice is grown wherever the soil is naturally rich to give a crop, and the rain sufficiently abundant to bring it to perfection. Most of the landed property of the country consists of rice or "paddy" which varies greatly, however, in quality and quantity, and consequently in value. The price of rice lands varies according to the soil, facilities of irrigation, distance from the centres of population, and returns they are capable of yielding. Some lands only 30 rupees to 40 rupees per para (about 1/20th of an acre); others cost up to 70 rupees (say, 156 per acre). The Government compensation lands taken for public purposes is only 14 rupees an acre. Land may be said to be worth generally 5 years' purchase. The produce of rice lands in some ranges from fivefold to thirtyfold. There is a general complaint that the land is deteriorating and is less than in former days, which the natives ascribe to diminished attention to sacred rites, but which arises from exhaustion of the soil through want of proper cultivation. In the hill districts, where tillage is more careful, requiring better attended to, and the sun and the clouds and rainfall being less, the yield has sometimes been known to be fortyfold; but

farmers think they are well off with fifteenfold at each harvest—i.e., twice in the year—and throughout the greater part of the country seven or eightfold, or in the south twelve to fifteenfold must be put down as the usual return. As it costs at least two paras (about two-fifths of a bushel) of grain in wages to sow one para of seed, a return of at least three times the seed sown is necessary to repay expenditure. A tenfold increase would be 80 paras, or 32 bushels, of "paddy" or rice in the husk. When cleaned of the husk this is reduced to half the quantity—say 16 bushels—weighing on an average 64 lbs. per bushel when raw. Old rice would be lighter, down to about 59 lbs. The produce, therefore, of an acre of good rice land may be averaged at 1,044 lbs. The total acreage of rice land under cultivation in Travancore is not exactly known, but a fresh survey and re-assessment are about to be undertaken. The survey of eighty years ago places it at about 400,000 acres; but since then much waste land has been brought under cultivation, and the total acreage cannot probably be taken at less than 500,000 acres. Whereas at the beginning of the century Travancore exported large quantities of paddy and rice (in 1843 no less than 281,000 candies of 554 lbs. each), and imported but a small quantity, the case is now totally reversed—exports being only about 70,000 rupees to 80,000 rupees in value, and imports (duty free) having risen from 14 lacs of rupees seven years ago to 13½ lacs in 1879. The produce of the country is, therefore, not sufficient for home consumption at the present time. This arises not only from the diminished production already referred to and from increase of population, but also from the general improvement of the circumstances of the lower castes, who can now afford to eat more rice in place of, or in addition to, fruits and vegetables, coarse roots, and inferior grains. Supposing the cultivated area of rice to be 500,000 acres, and the joint produce of the two crops fifteenfold, or 1,568 lbs. per acre; this divided amongst a population of 2½ millions would give 312 lbs. of rice per head per annum for consumption. Imported rice to the value of 13½ lacs of rupees would give (at a chukram per pound) 15 lbs. per head additional.

#### COCOA-NUT.

The cultivation of the cocoa-nut extends over the whole of Travancore, which has hence been facetiously called Cocoonut-core! Forty-four years ago the total number of cocoa-nut trees was 11,100,000, and the increase since has been so considerable, much waste land having been planted with this valuable palm, that the present number cannot be estimated at less than 15 millions. These are almost invariably too closely planted to obtain full advantage of sun and air; but supposing they stood at the moderate distance of 20 feet apart (which is 109 to the acre) the area covered would amount to 137,000 acres. The soils best suited for the cocoa-nut are the sea-shore, the banks and alluvium of rivers, and level lands exposed to the sea-breeze; these conditions abound in Travancore. Inland on the mountains the cocoa-nut will grow, but not bear fruit. The young plants generally require watering for the first two or three years, and must be protected from the inroads of cattle until they rise some feet above the ground. Ashes are supplied as manure at the beginning of the wet season, and the ground opened about the roots of the trees, which come into bearing some eight or ten years after planting. A cocoa-nut plantation is one of the most easily managed and most remunerative products of the country. The natives have but to put down the nuts and guard the trees more or less while attending to their other employments, and in due course, a permanent and profitable plantation is created. Europeans, however, seldom attempt such an investment, and few who have done so have succeeded in it. The price of 100 ordinary trees in the southern parts may be stated at about 400 rupees. These would pro-

It has been estimated that 60,000,000 of nuts and 15,000 candies of oil are annually consumed in the country. The trees are sometimes tapped for a few months, to procure the sweet juice, which, boiled while fresh, gives a palm sugar, and kept a day or two till it ferments, becomes toddy, a slightly intoxicating drink, somewhat like beer. The toddy also is distilled into arrack or native spirits. Other palm trees are also cultivated. Next to the cocoa-nut comes the palmyra, which is grown only in the drier districts towards Cape Comorin. The palmyra, with its sweet sap and sugar, leaves, timber, and fruit, furnishes a living to a great number of the Thanar caste in Travancore, and in Tinnevely. The number of trees in 1880 was about 6,000,000. It is probable that no considerable increase has taken place since, as old trees are in demand for their timber, and the slow growth of this palm discourages planting. From 160,000 to 24,000 cwts. of the sugar (jaggery) of this palm are annually exported, worth something over 3½ rupees per cwt. The beautiful areca palm is planted in damp, clayey soil, on the banks of tanks and rivers. Unlike the cocoa-nut it will thrive at a distance from the sea, and on the hills. It is grown very largely in North Travancore, whence the nuts are carried to the south by Syrian and other traders. The trees will grow two or three feet apart. The areca begins to bear in five years, and continues to produce for twenty-five years. The nuts are sold wholesale at six or eight chuckrams per thousand, and retail in Trevandrum at from eight to thirty-two for a chuckram, according to season and demand. 3,500 candies are annually exported to Bombay and other ports, the value of which is about 4½ lacs of rupees.

#### YAMS.

Roots, vegetables, and fruits form a considerable proportion of the food of the population in Travancore. The forest and hill people dig out wild stringy yam-roots from the jungle as food in the hot season. Every native grows something, if he can, around his own dwelling for home use. The principal cultivated root-crops are yams (*Dioscorea*) of various sorts, the small tubers of which are planted out in the beginning of the rainy season and dug again within a year. Some of these roots grow, under favourable circumstances, to a large size, up to four feet in length and one in diameter.

made in the year 600 B.C.; it was the Christian era that the art made advances. In the year 1223 A.D., were made in manufacture and design. From that date to the sixteenth centuries of Owari, Hizen, Mino, Satsuma were established. The Raku ware, was first made at Kioto, at the sixteenth century. The best of which is still the most admired, was Hizen, in 1580 to 1585: the old 8 1592. Consul-General Van Buren's clays are found in nearly all parts and the different kinds are usual proximity, and close to canals is of considerable advantage, as of transport. In all cases every ware in the manufacture of pottery is state; there is no necessity to manufacture fusible clays as is done in other and which adds considerably to it. One of the peculiarities in the clay that it contains both the fusible and in such proportions as to make a light cent, and durable porcelain. At As is a clay found which contains 78½ and 17½ per cent. of alumina; for the delicate, translucent egg-shell addition of any other matter. From a clay is taken which has 60 per cent. of alumina; from this the made. Potters' clay is found in the provinces of Yamashiro, Hoki, Higo, Owari, Mikasa, Idzumi, Mutsu the whole of Japan there are 283 clay is deposited; many of these are clays, but they are all fitted for various kinds of pottery. These are powdered by means of what are pounders, worked in some localities but the work is often done by hand then dried, and stored on boards or dough does not go through the process. The shaping is almost exclusively done by wheel, which is set on a pivot work. As a rule, the wheel is turned self, but in Hizen it is kept in motion

re; these kilns are so constructed that the s from the lowest one, in addition to which has its own firing place. The result of this on is that the upper ones are by far the ted, and the ware is arranged accordingly; h requires the least baking, in the lower kiln, which requires the greatest heat, in the these connecting kilns have the merit of being g, but they are usually small and badly con- and the heat in none of them is uniform. The ade from the silicious clay and potash extracted l ashes. This potash is not a pure white, and nts for the dirty colour usually to be observed ed Japanese ware. In different districts the varies. For instance, in Owari the greater e ware is painted a cobalt blue—the cobalt ore ad in the bluffs near the clay deposits, and is ainting the cheaper wares, and for this pur- an cobalt is also employed. The painting It is generally done on the biscuit before

In several districts a very handsome ware nd painted on the glaze. For this kind of he colours are mixed with a silicate of lead sh, and baked the third time in a small a low temperature. The colouring oxides in hose of copper, cobalt, iron, antimony, e, and gold. Japanese porcelain painting ived into two categories, decorative and the first is used to improve the vessel upon is placed, and this class includes all the pt that of the province of Kaga, which ae under the head of graphic, as it delineates ades, occupations, sports, customs and cos- he people, as well as the scenery, flora, and the country. "Owari ware" is made in ace of that name; it is not as translucent, er and more tenacious than some of the ufacture. The principal potteries are at a ulled Sêto, twelve miles from the sea; in ge there are more than 200 kilns. The oostly painted a cobalt blue, and is merely ative kind, consisting of branches of trees, rers, birds and insects, all these being copied ist from nature. All the Owari ware is true lain, and is strong and durable. In Hizen, of wares are manufactured, the best known r the "Eurari," which is made at Arita, but Eurari. The colours in use are red, blue, d gold; these are combined in various pro- ut, as a rule, the red predominates. Generally e of the vessel is divided into medallions of hich alternately have red, blue, or white back- ith figures in green or blue and gold. The porcelain sold at Nagasaki is made in this rom Arita clay, and this is made from clay admixture of fusible matter except that by the clay naturally. The province of is noted for cracked ware. It is only very few years that large vases have ufactured, and in earlier days the old , confined to small vessels. The glaze is a alumina and potash, and the best ware has a et-work of the finest crackles; the painting , and flowers, and noted for its delicate lines red, and gold. In Kioto the ware manu- s very similar to that produced in Satsuma, lighter and more porous, the decorations are y the same, being of birds and flowers. There ption of ware made in Kioto, called "Eraku," body of which is covered with a red oxide of over this mythical figures of gold are traced. duced in Kaga is *faience*, and in the style g is unlike any other in Japan, the predomi- lour being a light red, used with green and e designs with which it is profusely decorated grasses, flowers, birds, and figures of all people, with their costumes, occupations,

and pastimes. The "Banko" ware is made at the head of the Owari Bay; it is an unglazed stone-ware, very light and durable, made on moulds in irregular shapes, and decorated with figures in relief. On the island of Awadji, a delicate, creamy, crackled, soft paste porce- lain is made. The figures used in decoration are birds and flowers, but outlined by heavy, dark lines. Consul Van Buren is of opinion that, at no distant day, Japan will be one of the foremost competitors in the pottery markets of the world, on account of the great variety and excellence of the clays, their proximity to the sea, the cheapness of labour, and the beauty and originality of the decorations. Already this important industry has been greatly stimulated by the foreign demand, and by the success of Japanese exhibitors at the Exhibitions of Vienna, Philadelphia, and Paris.

### GOLD MINING.

The following report by Mr. Thomas Price to the Chairman of the Placerville Gold Quartz Company, Limited, dated San Francisco, April 16th, 1881, refers, in part, to Mr. A. G. Lock's paper on "Modern Gold Mining," read before the Society, January 19th last:—

"In answer to your favour of the 8th ult., on the subject of gold amalgamation as carried on at the Placerville Mill, I take very great pleasure in replying in detail.

"1st.—Description of mill:—The mill has twenty stamps, each stamp being of an average weight of 800 lbs., each battery of five stamps is furnished with a self-feeder. The self-feeders are connected with a large bin, having a capacity of three hundred tons of quartz; the floor of this bin is placed at an angle of 50 degrees, so that the quartz slides by gravity to the self feeders. The quartz is delivered from the mine by a self-acting tramway to this bin, the fine material passing through a grating, the coarser lumps remaining on the floor of the rock-breaker, both the fine and crushed material falling by gravity into the fore-mentioned bin, so that the ore passes from the mouth of the shaft into the battery, without the aid of any manual labour, with the exception of the labour in placing the large pieces of quartz into the rock-breaker. Cut 1 (enclosed herewith) will serve to show you how the self-feeder is attached, as well as the interior arrangement of the mortar. Cut 2 will show the kind of mortar in use—the gold one, of course, and not the silver one. The mortar has but one discharge, and that in front; the screens are made of thin slotted Russian iron, equal to 450 holes to the square inch; inside of each battery in front is a slip of silver copper plate, 8 in. in width by the total length of the battery. Immediately in front of the battery again is a large silver-plated copper-plate, equal to the total width of the mortar by 3 ft. in length, in front of which is placed again 20 ft. 18 in. sluice, the bottom of which is lined with silver-plated copper-plates, constantly kept in a bright condition. The tailings are now passed over what are known as Hendy's concentrators (there being one for each five stamp battery). Cut 3 (enclosed herewith) together with a printed description of the machine, explains itself. The tailings are now again passed over 20 ft. blanket sluices, and afterwards on a 50 ft. of coarse canvas sluices, or rather sluices lined with such material, and finally over 64 ft. of riffle sluices. The material caught on the concentrators and blankets is passed through an amalgamating pan, and settler, and agitator. Cuts 4, 5, and 6, and the accompanying printed description will explain this part of the operation. The material saved on the coarse canvas and riffle sluices are further concentrated in a Cornish buddle, as are also all the tailings from the amalgamating pan and settler. The quantity of quick-silver placed in the mortars or offcers is regulated by the appearance of the copper-plate in front of the battery ;

ON 21ST. A LATER FORM WAS PROPOSED, AND I WAS A SUB-  
 scriber to the *Journal* of this Society for many years.  
 (1st.) In the matter of 'gauge of gratings or screens.' The size of the screens should depend entirely upon the fineness of the gold in the quartz. If the gold should be diffused in a finely divided state through the quartz, it is evident that finer crushing must be had than if the gold were coarse. I have given the size of the perforations of our screens. (2nd.) All the protection to the mortar by having the dies rest upon a layer of sand has always been in use. We have not had any broken mortar as yet. The stamp-heads and the dies upon which they strike are of the same size; this we consider a protection to the mortar and stamp-head, that is the layer of sand under the dies. With such fine gold as we have to deal with at the Placerville, we could not expect much fine gold caught in this material. We rely upon our amalgamated copper-plates inside of the battery for this purpose, and I have no hesitation in stating that this is by far the best way to catch the maximum amount of gold. In the early days of gold mining in California, the stamps were used simply for the crushing of the ore, the amalgamation was conducted on the outside entirely, the only gold caught in the battery being coarse particles that could not pass through the screens. Experience has taught the mill men here that this latter method is not only more expensive, but by far less effective. I cannot agree with Mr. Lock when he states, 'I venture to assert that this system of putting mercury into the stamp coffers and using amalgamating plates, is radically wrong.' The difficulties that he speaks of, viz., the loss of quicksilver flooring, does not trouble us. I also claim that the particles of amalgam passing through the screens are caught either on the copper-plates in front, or on the Hendy concentrator, and if any escapes here, why we have the blankets, coarse canvas and riffle sluices, and finally the Cornish buddle.

"The last few weeks I have had some experience with the system designated as 'mercury riffles,' and mercury troughs, as fully described in Mr. Lock's paper. I had to examine a mine where they were in use, having been put in and erected by an experienced Australian mill man. I found the tailings containing an abnormal quantity of gold. The owners found it necessary to change this system to amalgamation on copper-plates inside the battery, with the usual outside

quartz mines. At a very large n large piles of tailings had accumulated I have had occasion to sample sent to be very rich, but, as them sufficiently rich to pay for the very popular thing for a superfluous mine is good, plenty of gold in the rebellious that it is impossible to such a mine have I had occasion to sorrow of the stockholders, found character was due entirely to the contained but little gold. I ha stating that, with proper care and I have described as in your mill as effective for the quartz we have to one described by Mr. Lock. Wha on the mortar plates, copper-plat concentrator, and the blankets a boxes, and Cornish buddles w endeavoured to cover the whole an not, please let me know, and I wil tional information I may have. I guidance as soon as I have time of all parts of the mill, explaining

[This report has been communi who has sent the following remark

The above report, by Mr. Thom of, and in answer to, a list of que addressed to all the gold-mining purposes of my forthcoming book c rence and Extraction."

I am pleased to be able to ta publicly, to thank Mr. Price for hi answering my questions, and I ca good example will be followed by a similar list.

With regard to his comments on the Society of Arts on the 19th c not think the pages of the Society place for a lengthy discussion; I him, and all others interested in t where the different systems adop will be compared and fully discu help, meantime, remarking that in the matter of loss of gold is s

r. Geo. J. Firmin states that in the Black Hills, etc., "they only obtain from 10 to 15 per cent. of gold," and that the general result of his inquiries about the country is, "that not more than 50 per cent of the assay value is recovered on the average."

Mr. Edwin Gilpin, A.M., F.G.S., the Inspector of Mines for Nova Scotia, reports that since returns have been collected, which enable him to ascertain results, 50 tons of pyrites, containing on an average 4 dwt. of gold, and 4 oz. 17 dwt. silver, with a value of £10 10s. per ton, have "been thrown away; in other words, over a million of dollars has been thrown into the brooks and swamps during the last 18 years." In answer to me in March last, he characterises this loss as due to the fact of "the chief idea being to pass as much material through the mill, and turn the tailings into the nearest brook."

Mr. Walter A. Skidmore's "table of the losses sustained in gold-mining countries" referred to above,

	Per cent.		Per cent.
Edmonton .....	35	Australia .....	25
Wagay .....	50	Colorado .....	40
Idaho .....	66	California .....	27

I have now lying before me a letter written in February last, by Mr. F. Guinness, warden and resident magistrate of the Collingwood goldfields, Nelson, New Zealand, in which he speaks of the melancholy fact that, through the inadequacy of the appliances and the want of knowledge how to extract the gold, the district, after several trials, has been deserted, and gold-mining abandoned, "little or no gold being obtained, yet the assays of the quartz gave results of most hopeful nature, as much as 4½ ounces of gold to the ton having been obtained from stone which Dr. Hector and myself assayed out of the reef."

It is to conclude, it appears to be owing to the nature of the ore with which Mr. Price has to deal, rather than to the efficacy of the appliances employed, that we see so little loss, for we find that the Idaho Company, Grass Valley, California, whose appliances are of the most elaborate character, extending the great length of 270 feet from the centre of the stamp heads, obtained 27 per cent. of their gold, obtaining 47·90 dollars, and losing in their tailings 18·67 dollars per ton of ore.

ALFRED G. LOCK, F.R.G.S.]

## PHONONES AT THE PARIS ELECTRICAL EXHIBITION.

Our Paris correspondent of the *Times* sends the following description of the use made of the microphone at the Electrical Exhibition, in order to give to numbers of people in the Exhibition the pleasure of listening, at night, to the companies at the Opera at the Théâtre Français. Rooms have been fitted in the galleries, each with a number of pairs of microphones. Two rooms are devoted to the Opera and to the Théâtre. The former is the more interesting, for there the actions and features of the performers are of less importance. You enter the room in groups of perhaps ten at a time. Each one advances to a stand and seizes a pair of telephones, which he places to his ears. Each of these is connected with a microphone on the stage of the Opera, one to the right, the other to the left of the prompter, and inclined towards the singers. The microphone to the right hears the prompter is connected with the telephone to our right ear, the one to his left is connected with that to our left ear. Thus, while the singer moves to right or left the sounds increase or diminish in the right or left ear; when they cease or recede the sounds increase or diminish in the right or left ear, and thus we are able to appreciate their move-

ments, and it becomes difficult to believe that the performers on the stage are not directly behind the wall which we are facing. So soon as the telephones are applied to the ears the glorious voices of the finest singers in Paris are heard by us undiminished in purity, beauty, or force, by the strange means which have carried them to us over a distance of a mile. The orchestral accompaniment is somewhat weak, owing to the arrangement of the microphones. We can almost see the singer move about, putting expression into the movement and action; and in no part of the Opera-house can you hear with greater (I might also say with so great) clearness and power as in this tapestried room in the Palais d'Industrie.

## THE PAPER MULBERRY TREE.

The United States Minister of Agriculture, in a recent report, calls attention to the largely increasing manufacture of cloth in China, Japan, and the Sandwich Islands, from the paper mulberry (*Broussonetia papyrifera*). In Tahiti and other South Pacific Islands, a species of cloth is manufactured from its bark, known as "Tappa" or "Kapa," and it is said that the finest and whitest cloth and mantles worn by the islanders and the principal people of Otaheite are made from the bark of this tree; it dyes readily, particularly in red, and takes a good colour. The following is the method employed by the native women of Otaheite in beating out the fibre. The cleansed fibres are spread out on plantain leaves to the length of about eleven or twelve yards, and these are placed on a regular and even surface of about a foot in breadth. Two or three layers are thus placed one upon another, great attention being paid to making the cloth of uniform thickness; if thinner in one place than another, a thicker piece is laid over this place when the next layer is laid down. The cloth is left to dry during the night, and a part of the moisture having evaporated, the several layers are found to adhere together, so that the whole mass may be lifted from the ground in one piece. It is then laid on a long smooth plank of wood prepared for the purpose, and beaten with a wooden instrument about a foot long and three inches square. Each of the four sides has longitudinal grooves of different degrees of fineness, the depth and width of those on one side being sufficient to receive a small pack-thread, the other sides being finer in a regular graduation, so that the grooves of the last would scarcely admit anything coarser than sewing silk. A long handle is attached, and the cloth is first beaten with its coarsest side, and spreads very fast under the strokes. It is then beaten with the other sides successively, and is then considered fit for use. Sometimes, however, it is made still thinner by beating it after it has been several times doubled with the finest side of the mallet, and it can thus be attenuated until it becomes as fine as muslin. Should the cloth break under this process, it is easily repaired by laying on a piece of bark, which is made to adhere by means of a glutinous substance made from the arrowroot, and this is done with such nicety that the break can scarcely be detected. In other islands the bark is kept wet and scraped with sharp-edged shells. It is said that the King of the Friendly Islands had a piece made which was 120 feet wide and two miles long. In Japan a species of cloth is made from paper derived from this tree. It is cut into thin strips, which are twisted together and spooled, to be used in the woof of the fabric, while the warp is composed of silk or hemp. About 250 pieces only are manufactured at the principal manufacturing place. The paper mulberry grows everywhere in Japan, and is a valuable tree, as furnishing the bast from which a large portion of the Japanese paper is made; the plants are reproduced in quantity by sub-dividing the roots, and in two or three

are produced are made of bamboo, split into very thin sticks, and united in parallel lines by silk or hemp threads, so as to form a kind of mat. This is laid upon a wooden frame, and the apparatus dipped into the vat, raised and shaken, so as to spread the pulp evenly, after which the cover is first removed, then the bamboo couch, with the sheet of paper. When a number of sheets have been thus prepared, they are pressed to exclude the water, and afterwards spread out with a brush upon boards and allowed to dry. The sheets are only about two feet in length, but sometimes sheets ten feet long are produced.

## GENERAL NOTES.

**Technical Instruction.**—A Royal Commission, consisting of Mr. Bernard Samuelson, M.P., F.R.S., Mr. Henry Enfield Roscoe, D.C.L., F.R.S., Mr. Philip Magnus, Mr. John Slagg, M.P., Mr. Swire Smith, and Mr. William Woodall, M.P., has been appointed "to inquire into the instruction of the industrial classes of certain foreign countries in technical and other subjects, for the purpose of comparison with that of the corresponding classes in this country; and into the influence of such instruction on manufacturing and other industries at home and abroad." Three is to be a quorum. The Commission has the ordinary powers.

**Agricultural Returns for 1881.**—The Statistical and Commercial Department of the Board of Trade have issued a summary of the returns collected on the 4th of June last, which shows the extent of land in Great Britain under wheat to be 2,806,067 acres, or 103,381 acres less than in 1880; barley, 2,442,405 acres, or 25,086 acres less than in 1880; oats, 2,901,195 acres, or an increase of 104,230 acres; potatoes, 679,431 acres, an increase of 28,499 acres over 1880; and hops, 64,128 acres, or a decrease of 1,577 acres. The total number of live stock in Great Britain on the same day is given as—Cattle, 5,911,524; sheep and lambs, 24,582,154; pigs, 2,048,034.

**Adelaide International Exhibition.**—Particulars of this Exhibition, which was opened on July 31st, by the Governor, have been received. The Exhibition is reported to have proved highly successful, the demands for space having been so numerous, that it was found necessary to

ourselves able to agree on certain papers were prepared by twenty or thirty inspectors, and we elicited from them criticism. Having received these reports, and agreed, further, that it thoroughly sifted, and the details were committed, consisting of Sir F. Sandford Cumin, the three chiefs of the Department Mr. Warburton, who had great experience of smaller schools, Mr. Sharpe, as inspector, and Mr. Fitch, for his connection with Over this committee Mr. Mundella's presence was ended, it was yet further sifted, by enlarged committee, including Mr. three other inspectors. This was Mr. Spencer, and the result is the document of the House.

**Population of Austria.**—The folk of the population of the several portions of the population of the several portions of the Central Empire for taking the census last December 2,829,021; Upper Austria, 760,878; Styria, 1,212,867; Carinthia, 348,671; Trieste, Istria, &c., 650,532; Tyrol, 107,384; Bohemia, 5,557,134; Silesia, 685,772; Galicia, 5,653,170; Dalmatia, 474,489; total for the Austro-Hungarian Empire last December, 22,130,684. This gives a total increase of 1,784,054, or 8.5 per cent. result as compared with the Hungarian increase for the ten years—11.1-24 per cent. The total population of the Austro-Hungarian Empire last December, was 22,130,684, to provinces had contributed only 197,394 rate of increase in the provinces of the monarchy averaged only .772 per cent. averaged during the last five years 1 more than one-third higher. The population of the Austrian provinces last December, 726,105; Prague, 162,318; Lemberg, 110,260; Gratz, 97,726; Vienna, 80,226; Czernowitz, 45,600; Linz, 41,

V. The plan which I have adopted for my lectures is, roughly, as follows:—First, I propose to make a few observations upon the ability to twist, plait,

regards lace. I heard a good deal about lace when I had the honour of serving on a committee which was formed to promote an Exhibition of Ancient Lace for the International Exhibition at South Kensington, in 1874. But when I came to be presented to some of the most splendid productions of the art, I found that hearsay did not give me much assistance in making myself really acquainted with these works. It was necessary to do more than express satisfaction at a beautiful piece of work, or to allow oneself to be carried away with enthusiasm over the interesting fact that some Venetian Dogress had actually made a certain length of vandykes. Throughout the collection shown at the Exhibition there was an immense variety of pattern and of workmanship. It seemed to me that I should be more likely to understand this if I applied myself to a careful examination of a few of the important specimens. Accordingly, a pocket magnifying-glass became a necessity, and through its help I began to arrive at some sort of classification of laces by stitches. As soon as I had satisfied myself as to the marked difference between needle-made and pillow-made lace, I began to study the catalogue and the descriptions printed in it. I confess to having been surprised, and inclined to doubt my eyesight, at the frequency with which my opinion clashed with the descriptions. It seemed as though tradition was more often than not exactly the reverse of personal experience. Some of the best traditions were only credible, subject to important "ifs;" others, however, seemed to gain in historic value as they harmonised themselves with results of actual observations. A sense of gratitude to the spirit which moved me to closely examine specimens, and not to rely too much upon traditions and so-called authentic records, required me to give you this little account of my experience in studying lace.

VII. From examining lace-work, with all the minute twistings, platings, and loopings of fine

some sorts of lace-making—has a sewing done by tailor birds. I temptation of quoting a passage book, which tells us how the tail hanging nest:—

"The bird chooses a convenient which hangs at the end of a slender row of holes along the edge, using in manner that a shoemaker uses his awments being very similar to each other not in material. These holes are and in some cases there are so many bird seems to have found some specimens making them just as a boy who has havoc on every piece of wood he the holes are completed, the bird thread, which is a long fibre from so much longer than is needed for performs. Having found its the tailor begins to pass it through the sides of the leaf towards each other kind of hollow cone, the point down a single leaf is used for this purpose bird cannot find one that is sufficient two together, or even fetches another with the fibre."

IX. You will, I hope, pardon a sion from the point we were con man's ability in twisting and I think we may take it that this sort of spontaneous invention. the development of certain nat the fingers. Therefore, where th fingers, and a governing intelli to plait, twist, and loop threads One might not expect to find t restricted to one nation, or to a world's history. Still, certain con especially favour the exhibition and plaiting ability, and perha such conditions is the exist quantities of articles like flax c of all kinds.

ids of twine are stretched in parallel out half an inch from each other, from front of the frame of the seat. Similar cords also stretched from side to side. Thus a square meshed foundation is made. The cords are intertwined—diagonally across the seats of some eight or twelve strings or so the seat, not unlike our modern cane constructed. This sort of plaiting and weaving, however, cannot be said to have pretence, and is not so germane to ornament as we call lace, as are fringed borders of sculpture upon Assyrian monoliths, as of Assur-nazir-Pal, about 800 B.C. (See Fig. 1.) The lines forming a trellis pattern in

FIG. 1.

Assyrian border, 800 B.C.

part of these borders appear to consist of plaited cords, very similar in their pattern to that which we see upon fringed borders of carpets now in the market, or to the whip thongs. On the mantle of the Assyrian the trellis pattern is rather more than those on the dresses of the attendants. The design is, however, quite primitive. Our English Bible lace is frequently of this pattern, but its meaning must be qualified by its due to the use of such a word in its own time. It is pretty evident that the word was used to indicate a small cord, since its decoration would be more commonly of that time as "purls," "points," or "knots."

If we look amongst the Greeks we seem to have the same. Upon the well-known red and black friezes of figures, clad in costumes which were decorated with ornamental patterns, but these were woven into, or embroidered upon. They were not lace. Many centuries before a marked and elaborately ornamented character infused itself into twisted, plaited, and thread work. During such a period the ornamenting borders of costume and architecture existed and underwent a few phases: for instance, in the Elgin marbles, where the edges appear along the loose flowing robes.

It is recorded that our "general parents" the garden of Eden, wore aprons of leaves,

overlapping one another, an arrangement subsequently modified for their scale armour by the Greeks and Romans. (See Fig. 2.) The scales of

FIG. 2.

Overlapping leaves of armour.

the armour were of leaf and billet forms, as were the edges of the under skirt and sleeves. (See Fig. 3.)

FIG. 3.

Overlapping scales of armour.

Fig. 3.) If you want to see an attractive example of this method of varying the line of the edge, the costume of Mr. Irving, as *Synoria*, in Mr. Tennyson's drama of "The Cup," presents you with one. Along the borders of Mediaeval costume, this custom of indenting the border was perpetuated. (See Fig. 4.) The French word, "dentelle," is

FIG. 4.

Cut, scalloped edge.

evidently derived from the tooth-shape of such scallops.

XIV. To continue, however, our rapid glimpses of fashion in patterns for bordering costumes and in decorative accessories to dress, which seems to have led up to lace. Mosaics, dating from the 6th century after Christ, preserved in churches at Ravenna, give us representations of early Christian saints, Cecilia, Crispina, Lucia, and others, attached to whose white head-dresses are fringes. Besides these, there are resplendent mosaics of the Empress Theodora and her ladies in waiting, all arrayed in sumptuous apparel, some of which is ornamented with dentations, and others with wavy and undulating borders. In 1078, Benedetto Antelami, recording the fashion of his time, wrought a patterned edging to the robe of the Virgin, who appears in a composition he carved in stone for an altar or panel at Parma. A border, consisting of a series of holes, no doubt cut out and worked upon

family, decorated the borders of the robes of the figures. But in mentioning these Italian instances of the fashion in borders of dresses, it must not be supposed that similar fashions had not also penetrated to other European countries.

XV. In Edward IV.'s time, in England,

"Cut werke was grete in Court and towns,  
Both in men's hoddies and also in their gowns."

but this "cut werke" is not cut work embroidery as we know it. It was the cutting out into shapes, the dentation or scalloping of the borders of stuff "hoddes" and gowns, as we find it with the Romans. (See Fig. 4.) This kind of ornamentation undoubtedly influenced the shapes in which most of the first laces were to be inserted, and we trace such shapes in "points" of the 16th century, an example of which I will show you (Fig. 5). Chaucer, too, in his Parson's tale,

FIG. 5.

Cuff trimmed with lace-work in "points," or Vandykes. Late 16th century.

gives us an insight into fashions of dress, when he deprecates "the superfluitie of clothing, which maketh it so dore to the harms of people, not only

The designs are to be umes and hangings, and besides rwn, consist of scrolls, arabesques, owers, foliage, herbs, and grasses; lace would be concerned, involve t work as none but practised lace

makers would be able to overcome. Twenty years later we have special geometric patterns workable by lace makers, who were at the threshold, so to speak, of the practice of their art. (See Fig. 6.)

FIG. 6.

Part of a border of needle-point lace, geometric design. About 1550.

At this time, about 1550, the "punto gropposi" (knotted work) is named. The designs, too, of the same time, for "punto in aria," are clearly geometric lace designs.

XVIII. Monsieur Aubry, member of the jury appointed to make awards of prizes to lace manufacturers, who exhibited specimens at the Great Exhibition in 1851, is one of the first of modern writers on the art of lace-making. For the ground-work of her "History of Lace," I find that the late Mrs. Bury Palliser, as all students of this subject must be, is indebted to him. M. Aubry says that Italy and Belgium dispute the honour of the invention of lace-making. Without attempting to settle the dispute, he says that we can easily imagine that the fabrication of lace in each of these countries was quite different, and thus having drawn upon our imagination, Mons. Aubry is assured enough to say that if Venice is the cradle of needle-point laces, at Brussels it is certain that the first pillow and bobbin-made laces were produced. After examining the evidence, which he brings forward to support his statement, as well as considering remarks made by Mons. Seguin in his "History of Lace," I have formed the opinion that so distinctive a method of using threads as that involved in ornamental lace-making has not a contemporary double origin; and in a later lecture I hope to show you a series of specimens which appear to indicate how elaboration of plaiting, twisting, and looping white threads developed according to the demands made upon workmen's ingenuity by the designers of patterns. The workmen's ingenuity developed two distinct classes of work, the one needle-point lace, the other pillow-made lace. The former is, undoubtedly, an offspring of embroidery, just as the latter is of fringes or twisted cords. Both, however, in respect of artistic pretence, are traceable to the pattern-books. We have noticed the appearance of "punto in aria" or needle-point lace, and that of "punto gropposi" or knotted work. A modification of the "punto gropposi" is the "merletti a piombini." (See Fig. 7, p. 774). In this specimen you would see that plaiting is used. There are no knottings, and few simple twistings. The first patterns for both plaiting and needle-point work then appear to have been made in

Venice in the 16th century, say about 1580, and thus M. Aubry's supposed double origin of lace vanishes, that is, if my statement be correct.

FIG. 7.

Plaited and twisted thread-work known as "Merletti a Fiombini." About 1580.

XIX. No sooner, however, are novelties produced, than imitations quickly follow. The twisted and plaited thread-work was by some more easily done than needle-point work by others; and the Flemish, the chief spinners and weavers of thread, very naturally I think, were the first imitators of Venetian patterns of this sort of work, which was plaited on cushions. We have already seen that commercial relations long existed between Venice and Flanders. It had been chiefly carried on by ships, and this, of course, in respect of heavier merchandise, but in the 15th and 16th centuries an overland route via Augsburg, Cologne, and Bruges, was also used, probably for lighter wares. Copies of pattern-books, and dentated and scalloped trimmings, were no doubt included amongst these lighter wares. It is not, therefore, surprising to find pattern-books, evident imitations of Venetian books, springing into publication along the route overland. At Augsburg and Cologne, and as far north as Antwerp, we know such books were issued. At this last-named city, possibly about 1540, one of the first of the foreign imitations of Venetian books of patterns was produced. It is called "A New Treatise; as concerning the excellency of Needlework, Spanish Stitch, Weaving in the Frame, very necessary to all who desire perfect knowledge of Seamstry, Quilting, and Brodering work, containing 138 plates."

XX. The mention of "Spanish stitch" makes one almost expect to find Spanish books on needlework. But, curiously enough, no such books corresponding to the Italian, German, Flemish, French, and English pattern-books have been found or known to have been published in Spain. Spanish stitch is now supposed to have been a black silk embroidery upon linen, and its use is assigned to the early 17th century. This is not a lace, however. Of the supposed manufacture of artistic lace in Spain, it may be convenient for me now to speak. It will, no doubt, be a matter of surprise to many, who are so accustomed to hear of and see what they are told in "Spanish point," if I say that Spain cannot be identified with the making of ornamental and fine white thread lace, as are Italy, Flanders, and France. Señor Riaño, an authority in these matters, writes that, "The most important ordinances relating to Spanish industries are those published at Toledo and Seville in the 15th and 16th centuries, and at Granada in the 16th and 17th centuries, and in none of them do we find

lace even alluded to." A Friar, Marco de Campos, 1692, preaches, "I will not and fail to mention the time lost these 1 the manufacture of 'cadenetas,' a word combined with silver; this extravagance reached such a point, that hundreds and of ducats were spent in this work, without destroying the eyesight, wasting away and rendering consumptive the women; it, and preventing them from spending with more advantage to their souls, of thread and years of time were was unsatisfactory a result." Señor Riaño argues from this that the Friar adopted, as a term meaning lace-work. But, he says "cadenetas" is chain stitch. He says that the fashion of the 16th century itself towards "points," and "dentel bands of insertion of lace-work, it might have more likely that the Friar would sumed such adornments with the fire of—naming them by their proper n "puntas," "randa," and "entredos." may, no doubt, have been inveighing sinful extravagance in the use of an embroidery; I do not think, however, safely rely upon what would be a misap as proof that Spain made lace; that she is well-known. Whilst the female po family embroidered, Cervantes, it is much of his "Don Quixote."

XXI. Ornaments made of plaited gold and silver threads, much in the some lace was made, were produced during the 17th century. Mention to be found in the ordinances of Towards the end of the century, No author of a work published in Barcel by M. Aubry, writes, that "edgings of gold, silver, silk, thread, and also made at Barcelona with greater per in Flanders." In the 16th century F part of the Spanish dominions. S always spoken of as Spanish Flanders Spain was indebted for a quantity o tured and artistic goods, linen and la I conclude, therefore, that the Bar making was more or less an imitat which had pre-existed in Spanish Apart from this, the gold and silver lace Venice, Lucca, and Genoa, preceded Flanders. It appears to me that Spa in the field of artistic lace-making Flanders, and France. As a great coo wealthy power, Spain, I think, in the 16 centuries, imported the greater pora fantastic and fashionable luxuries she Even the celebrity of the gold "Point d is due, I fancy, more to the use of by Spanish grandees, than to the pr Spain of a gold lace, better in design, in ship, and quality, than that from Italy. The manufactories at Paris and Lyons force, supplying the fashionable w gold lace in the 17th century. "Point d'Espagne" was, I think, a name given to gold lace by French and interesting to note that Beckmann in hi of Inventions," says that it was a fact the name of Spanish to all kinds o

Spanish flies, Spanish wax, Spanish green, grass, Spanish seed, and others. This sure establishes the value set upon the orn or title "Spanish," and, at least, that the custom of Spaniards was much by other nations. In concluding these ons as to claims that Spain may have for sidered an early maker of artistic lace, I te the following passage from Señor hich greatly affects the value of what herwise be a fact of importance contained Palliser's "History of Lace":—

withstanding the opinion of so competent an as Mrs. Palliser, I doubt the statement, find- ridence to support it, that thread lace of a very tistic kind was ever made in Spain or exported icle of commerce during early times. The lace h Mrs. Palliser mentions to prove this, as exist- ranada, a gift of Ferdinand and Isabella in the bury, is of Flemish lace of the 17th century."

. Of France and her connection with early king, there is not much at present to be said. ident that a great deal of foreign lace, rom Flanders and Venice, were imported ace, and that all sorts of prohibitions were prevent the expenditure of the French sign goods, and so, if possible, to encourage ifacturers to make articles for home con- n; but the importations went on, and was at this time unable to make laces to with those from Italy and Flanders. The s of commercial dictionaries and encyclo- Diderot, Savary, Roland de la Platiere, and vriting in the 18th century, give the names ificant little primitive twistings and plait- a "gueuse," "mignonette," and "cam- These bear about as much relation to fine aces as a flint instrument does to a Cellini's andle. Taste in manufacturing lace in vas not evoked until Frederic Vinciolo came about the end of the 16th century, and the Court of Henry IV. with varieties e thread work, including the geometric f Venice. But even Vinciolo's nfluence was and only laid the seeds of a condition in France, which enabled Colbert forty ter to induce Venetian lace designers and n to come over to France and to help in blishment of a number of places where ould be regularly made. Many of the earest to Flanders were judiciously chosen e new lace establishments. But the chief French towns subsequently most famous r its lace was Alençon in Normandy. Of ence of Alençon we shall hear more in the f our investigations of needle-point lace

I. Of incidents concerning workpeople en- n the manufacture of lace, we have little information. History is almost silent in of guilds, or bodies of lacemakers (if ere such) in the 16th century. Venetian might be expected to reveal some light is; but at present the search has not been iful. Documents exist to show that a dy, Bianca Capello, was able to monopolise king of certain laces for her own use, in nd that in 1582 Juan Isepo worked a l collar, very likely of Reticella work, for Morosini di Francesco. A note is given in

a pamphlet by Signor G. M. de Gheltot, of the foundation of a school of 120 lacemakers at Venice, by Morosina Morosini, in the 17th century.

XXIV. Valuable State records, from which some information might probably have been obtained about the Flemish lace trade, were burnt in a fire at Brussels in the year 1731. Private papers of nunneries in Italy and Flanders would probably be an interesting source to examine. Evidence, such as it is, points to lace-making having been at first an occupation of individual peasants, rather than of organised bodies of persons. Nuns in convents no doubt produced a good deal of lace, as well as children in schools; and by Italian trimming makers and French guilds of "pasementiers," probably much lace of a primitive kind was made. Lace of later periods, that is, from the middle of the 17th century onwards, can generally be identified with centres of manufacture, like Valenciennes, Mechlin, Brussels, Alençon, Honiton, &c. But of the earlier laces, excepting those done according to Venetian patterns, we have not much to rely upon for guidance.

XXV. The 16th century Italian patterns are sometimes named "punto Famenghi," "punto Genovese," and "punto Francesco;" but there is little variety in the style of the patterns, so that the names, even if they meant more than the celebrated "Point d'Espagne," do not give us new clues as to other centres of manufacture if they existed. These names were apparently pattern-makers' names for styles, intended to catch the fancy of the different people to whom they were dedicated, and may have been made in various towns in Italy, such as Rome, Venice, Genoa, Milan, Piacenza, and elsewhere. I am afraid, therefore, that much of the classification of early lace has to be somewhat vague.

XXVI. An elaborate design, for instance, is hardly likely to have been worked out by humbly trained peasant hands; it is more likely to have emanated from some place where workmen and women were employed for the purpose of lace-making, and where they had access to good patterns, plenty of materials, and so forth. Such conditions existed probably also in Italian and Flemish convents. On the other hand, simple patterns would, from the ease with which they could be executed, recommend themselves to makers of the less important laces, whose operations would have a tendency to become restricted to the repetition or modification of such simple designs, the sale of which would no doubt take place amongst the villagers, or else be promoted by some *Autolycus*, and such hawkers of wares, at fairs and markets.

XXVII. The excellence of much of the early lace is perhaps due in a great degree to the good taste of the wealthy, who bought and wore the work, Demand ruled supply, whereas now-a-days, supply seems to rule demand so far as beauty of design and quality of workmanship goes. There are few Mæcenases now. The recommendation of the salesman is a chief moulder of public taste. The salesmen in turn regulate the style and quality of the goods to be made, according to their opinion of public taste and fashion. Such relations do not seem to have existed when the great Alençon factories were established. For the

wealthy lace wearers, then, at that time, the number of lace workers was insignificant as compared with the number now. One might say that lace wearers could be counted by the thousand, whilst those not wearing laces were the millions. This is now almost reversed. The millions now wear it, or something like it. Louis XIV. and Colbert determined that French taste in lace should be good, and virtually took into their own hands the supply of lace to the country. From Alençon were sent out admirable patterns and exquisite workmanship, which were readily accepted by lace fanciers. Brussels unquestionably adopted styles of Alençon designs for her pillow laces, which in time superseded French needle-point laces. Our English pillow-lace workers adopted some of the Brussels patterns and some of the Mechlin; but English taste was easily gratified by less skilfully arranged patterns, and found sufficient pleasure in the peasant laces of Buckinghamshire and Devonshire. It is these patterns that a good deal of the machine-made lace imitates, though within the last three or four years there has been a marked phase of other more ambitious imitation in the machine-lace trade. Something akin to the rich patterns of ancient hand-made lace is now made by the machine, and to the majority this substitution of machine-made for hand-made goods is satisfactory. As a rule the difference between machine and hand-made lace is not detected by the many. If there is a difference, to some it is that machine-made lace, from some points of view, is the more wonderful and more to be prized of the two sorts of work. Setting aside any prejudices one may have, and reviewing the variety of forms wrought years ago, we may consider some of the circumstances of the production of laces. Sometimes laces were made in dim and dark cellars, so that the soft fragile threads should retain their elasticity, and not become brittle. A ray of light alone was allowed to fall upon the workwoman's cushion. What an expense of eyesight and health must then have taken place. Compare truly costly works produced in such circumstances, with the low-priced repetitions done in fast wiry cotton threads which grow with precise monotony of pattern in the bustle and clatter of machinery, at the expense of iron and steam, and one is perhaps inclined to be glad at the release of human labour from penalties like those which formerly accompanied lace-making. I do not think anyone can well say what may succeed to the mechanically devised and produced materials now called lace? They seem to satisfy present demand and to reflect the taste and ability of the age. Is it vain to hope for a revival of hand-made works? Is the time to arrive when machinery shall have exhausted itself in its endeavours to infuse into its productions the quality of hand-work—or has a period commenced when people shall be contented with mechanical instead of manual art? and so from this possibly pass on to a condition of indifference to fine artistic works of handicraft, which not many years since were reported to have been pronounced by a philosopher and leader of opinion to be but the rubbish of human labour.

XXVIII. In my next lecture I hope to deal with the various needle-point laces, and besides the examples shown on the screen there will be a

few fine specimens of lace, and some pictures. I must not conclude my remarks without acknowledging the advantage both you and I have received from Cunliffe-Owen, director of the South Kensington Museum, who kindly caused many of the varieties of lace to be made, as well as William Drake and Mr. Edmund Dreelent specimens, some of which have been and others photographed, by Sergeant R.E., the able assistant of my friend Abney, R.E., F.R.S.

## MISCELLANEOUS.

### NATIONAL TRAINING SCHOOL FOR

The fourth general report, dated Easter, just been issued, and the following is an abstract of its contents:—

The Committee of Management have the honour to submit, for the information of the founders, shareholders and subscribers generally, the following statement of the condition and proceedings of the school for the past year.

*Scholars and Private Students.*—The body has undergone some slight changes during the year, e.g. seven scholars have resigned their scholarships in order to devote themselves entirely to their own studies in Italy, and one has forfeited her scholarship by failure to attend the school. Three of these vacancies have been conferred on new scholars, and one has been cancelled by the founders for want of continuance, and three are still vacant.

The number of scholarships is now, then, 23 are held by males, 66 by females, as has been already said, are vacant.

Arrangements having been made for the admission of private students for periods of not less than one year in advance, there were admitted of that class during the year now females and four males. Such students are the same privileges, are taught by the same in the same classes, and are subject to discipline as the scholars. Previous to admission musical abilities are tested by examination.

*Attendance, Conduct, and Studies.*—The attendance of the scholars, save in cases of sickness, was regular and punctual; and their general behaviour was very satisfactory. The instruments and books for study are, of course, substantially the same as at the time of the issue of the last report. At present 67 students are cultivating the piano as the principal subject of study; 22, singing; 14, five, the organ; and one, the flute. The piano students continue to attend the harmony classes, the vocalists attend the Italian class, those who are competent for it have had counterpoint and composition. An orchestra has been established and placed under the direction of F. H. Cowen. It embraces all those students upon orchestral instruments, and meets for four hours per week. During certain times

dical concerts in which all the scholars in turn take

*Use of Study, and Examinations.*—The period covered by the present report includes three school years, viz., the Midsummer and Christmas terms of 1880, and the Easter term of 1881. At the end of the summer term the fourth annual examination of the school took place in the West Theatre of the Royal Albert Hall. The professional examiners included Sir Samuel Costa, Sir Julius Benedict, Sir George Grove, and Mr. Charles Hallé. Mr. Hullah and Messrs. Ella being too ill to attend, the Committee of Management, at the suggestion of Dr. van, the principal of the school, invited Messrs.

Goldschmidt and Henry Leslie to join the Board of examiners, and these gentlemen courteously accepted invitation. Owing to some unfortunate want of understanding between the authorities of the school and examiners, the examination, though going on for three days, was not formally conducted; and in a report which the examiners made to H.R.H. the Prince of Wales, it was admitted that the examination which had been held was not an examination in the strict sense of the word, and neither fair nor advantageous to master skill. Under these circumstances it was arranged that another examination of a more strict, formal, and serious character should be held at the earliest convenience of the examiners.

The ordinary terminal examination for the Christmas term was held in the school on Saturday, Monday, and Tuesday, the 18th, 20th, and 21st days of December. It was conducted by Drs. Sullivan and Stainer, who had the assistance of the Board of Professors and of several professors. It extended to the principal subjects of study, to modulation, sight reading, figured bass playing, playing from vocal score, playing from full score, and transposing song accompaniments. On this occasion Dr. Stainer reports:—"The examination this occasion was directed to a class of subjects in which the scholars had not been hitherto tested, namely, composition at sight, playing from figured bass, from score, &c. The results showed that a considerable amount of proficiency had been attained by the majority of students, although the novelty of the test did so much nervousness, especially among the younger pupils, that the task of the examiners was easy. In all examinations on these special subjects it will be found that players on polyphonic instruments such as the piano and organ, attain the highest standard, players on string instruments as degree of proficiency, whilst vocalists rarely rise them to any marked extent. In the examination of the principal studies of the scholars, results were favourable. The signs of improvement in execution and taste, anxiously watched for by the examiners, were not deficient, although some few pupils were that they never could rise above a medium standard of proficiency, owing to their want of natural talent."

Towards the end of the Easter term 1881, arrangements were made at the request of H.R.H. the Prince of Wales, for holding the examination which had been invited by the committee of management at the suggestion of the examination held last Midsummer.

Interest which the Prince of Wales felt in the school, as the suggested nucleus of the proposed Royal College of Music, led his Royal Highness to appoint a body of examiners himself, and to give them instructions for the formal discharge of their duties.

Full report, dated April 23, 1881, signed by Henry Leslie, Chairman; Julius Benedict, Knt.; Michael Costa, Knt.; W. G. Cousins; George J. Elvey, Knt.; A. Doc.; Otto Goldschmidt; and John Hullah, Esq., was presented to his Royal Highness.

*Position and Prospects of the School.*—The committee of management having been informed that the executive committee, acting with his Royal Highness the Prince

of Wales on behalf of musical education in England, would not be in a position to take over the school, as part of the proposed Royal College of Music, at Easter, 1881, the period when the present scholarships expire, it was resolved at a meeting, held on the 13th November, 1880, that it was desirable to continue the school for one year pending the granting of the charter, and that application should be made to the founders of scholarships and other subscribers to renew their subscriptions for that period. In pursuance of this resolution, an appeal was issued by H.R.H. the Duke of Edinburgh, dated 29th February, 1881.

The appeal resulted in the renewal of sixty-three scholarships, the foundation of eight new ones, and the contribution of £510 10s. in new subscriptions. These resources, together with the balance in hand, amply suffice to keep the school going for another year; and the professors without exception having expressed their willingness to continue their respective services, the prospects of the school for the coming year are very satisfactory.

*Donations and Loans.*—Three framed engravings on musical subjects have been generously presented to the school by H.R.H. the Duke of Edinburgh. The corporation of the Albert Hall continue most munificently to permit the school to use one of their theatres for choral and orchestral practice and for examinations. The great firms of pianoforte manufacturers, Messrs. John Broadwood and Sons, Messrs. Chappell, Messrs. Collard, and Messrs. Kirkman, also still most liberally afford us the gratuitous use of their excellent pianofortes.

## THE MICROPHONE IN OBSERVATORIES.

M. Van Rysaelberghe's idea of using the microphone in observatories has been adopted in the Observatory at Geneva, and by the aid of the instrument, in combination with the telephone, the sound of the beats of the normal pendulum have been made audible in every part of the building. M. W. Meyer, assistant-astronomer at the Geneva Observatory, has given the following details in the *Archives des Sciences Physiques et Naturelles*. The microphone is fixed to the exterior of the framework in which the pendulum swings. One of the conducting wires connects one pole of an ordinary sized Meidenger cell with the microphone, whilst a second wire goes from the other pole of the battery through a telephone and commutator with three binding screws, to the microphone. The two wires coming from the coil of the telephone are very fine, and are interlaced so as to form one supply cable. By this means the telephone can be carried into any part of the Observatory, wherever required. Thus, it can be carried up to the top of the building and the course of the stars watched, whilst the observer listens to the number of beats of the pendulum. By means of a second telephone, with one wire fixed to the third binding screw of the commutator, the pendulum beats can be heard equally well in the lower rooms of the Observatory, as in the upper portion. The Observatory is also connected with the Hôtel Municipal, so that the beats of the electric clock regulator in that building can be heard in the Observatory and compared with the beats of the pendulum in the Observatory. At a certain hour the person whose duty it is to regulate the regulator in the Hôtel Municipal gives notice to the Observatory, by ringing a bell, that he is at his post. He then connects his telephone line, and the astronomer tells him how far the regulator is wrong; he puts it right, and re-establishes the microphonic communication, in order that the astronomer may test the regulator again by the pendulum. All this is done in about five or seven minutes. The apparatus is stated to have always worked well.

## GENERAL NOTES.

**Australian Fruit for England.**—A writer, in a recent number of the *Colonies and India*, draws attention to the likelihood of our obtaining supplies of fruit from Australia. He remarks that "soft fruits" cannot satisfactorily stand the length of the passage and the heat of the tropics; but apples, pears, oranges, and walnuts, and even grapes, may fairly be expected to do so. A recent consignment of apples failed to realise a sufficient price to pay the freight; but the freight was unduly high, and the fruit arrived at a time when the market was glutted with Canadian produce. Several cases of grapes have been landed in excellent condition; and there would appear to be no reason, if care is given to the gathering and proper packing of the fruit, why grapes of the best quality should not be placed in Covent-garden towards the close of the winter, and compete favourably with our hothouse produce, whilst the best Tasmanian pears would not fail to lower the price of a guinea the half-dozen commonly asked for Jersey fruit in spring. Both grapes and pears would pay better than oranges, but the latter fruit will unquestionably stand the passage best. The packing of the fruit is the main point; but it must be carefully gathered when free from dew, and packed when not heated by the sun. The air should not be entirely excluded from the fruit, and the use of dry sea-weed is recommended for lining the cases; while if each pear, apple, or orange is separately wrapped in tissue paper its condition will be materially improved. These fruits should be packed ripe; but grapes may be left to mature on the passage. Tasmanian jams are now to be bought in London shops; and, with the fast steamers now running, many of them provided with ice chambers, there is no reason why a little care and experience should not result in Australian fruit being placed in the English market in sufficiently good condition to ensure a remunerative return to the exporter.

**Indian Exhibition.**—An Exhibition of the products of India is to be held in December of the present year, and continued during January, 1882.

**Congress of Electricians at Paris.**—The *Chambre Syndicate d'Electricité* has organised an international meeting of electricians to take place in Paris between the 1st and 16th of October. *La Revue Industrielle* says:—"The congress will treat of theoretical questions; the meeting will lend itself by preference to the purely industrial and commercial side of the question. It will study the ways and means necessary to enable electricity to take the place it merits in our advanced civilisation." The president of the *Chambre Syndicate d'Electricité* is M. H. Fontaine, and the president of the organisation committee is M. Armand-gaud, jun., to whom all papers, &c., intended to be communicated at the meeting should be sent before the 15th September, at No. 10, Rue de Lancry. M. Boistel has been appointed treasurer of the meeting, and to him the subscriptions, amounting to thirty francs for each member, should be addressed. These subscriptions are intended to defray the cost of publishing the papers that may be read.

**Panama Canal.**—The engineer in charge of the boring operations being carried out for the Panama Canal reports, according to the *Engineer*, that the borings had proceeded to a depth of about 100 ft. from points, the altitude of which varied from 200 ft. to 260 ft. above the level of the sea, without encountering the rock *in situ*. The material was apparently a more or less dense breccia or conglomerate of rounded fragments of rock embedded in argillaceous matter. The fragments of rock are in a state of decomposition, and, after exposure to the atmosphere, a slight touch will cause them to separate into concentric layers, leaving a compact central nodule. The existence of these globular blocks on all sides, and distributed over the surface through the debris, leads to the inference that the geological structure of the soil to be cut through will prove to be similar throughout, more especially as the rocks met with most abundantly on the Isthmus are conglomerates and tufa.

**Railways in 1880.**—Although the "Railway Returns" for 1880 have not yet been issued by the Board of Trade, some of the main features of the movement, as ascer-

tained from the "Statistical Abstract for the U. Kingdom from 1866 to 1880," has been given in the following figures the returns for 1879 can be compared with those for 1880:—

## Length of railways open in the United Kingdom

1879 .....	17,696 mil
1880 .....	17,945 "

## Total capital paid up in shares and loans:—

1879 .....	£717,008,4
1880 .....	728,621,6

## Number of passengers conveyed (exclusive of ticket holders):—

1879 .....	562,732,8
1880 .....	603,884,7

## Number of passengers per mile:—

1879 .....	31,8
1880 .....	33,6

## Total traffic receipts:—

1879 .....	£59,395,2
1880 .....	61,958,7

## Traffic receipts per mile:—

1879 .....	£3,3
1880 .....	3,4

## Working expenses:—

1879 .....	£32,045,2
1880 .....	33,502,8

## Net traffic receipts:—

1879 .....	£29,731,4
1880 .....	30,985,0

**Lead in Germany.**—The returns for the lead in Germany, during 1880, show that 853,951 produced, against 825,567 cwt. in 1879, or 27,488 than in the former year.

**Australian Colonies.**—A statistical return relative positions and aggregate importance of the Colonies at the close of the year 1879, has been lately at Sydney, from which it appears that the total area miles is 2,580,282, and the estimated mean 2,659,779; the revenue was £15,927,488, made up:—New South Wales, £4,475,059; Victoria, £2,438,161; South Australia, £1,662,498; Queensland, £1,384,905; Tasmania, £875,367; Western Australia, £196,438; of telegraph lines, 26,841½; of telegraph 43,816½. The number of horses, 1,064,640; of cattle of sheep, 65,914,236; of pigs, 822,039. In these New South Wales is greatly in excess of the other thus of sheep the number in New South Wales is: while in the other colonies the numbers stand as Victoria, 8,651,775; South Australia, 6,140,396; land, 6,065,034; Tasmania, 1,834,441; Western 1,109,860; New Zealand, 13,069,338. In respect Queensland nearly equals New South Wales, being—New South Wales, 2,914,210; Victoria, 1,286,217; Queensland, 2,800,619; New Zealand, 129,091; Western Australia, 60,617; New 578,430.

**Gold Production.**—It is reported that the total of gold in the whole world last year was 118,000, nearly half of which was mined on the continent of the product of silver is said to be 94,000,000 dols. 76,000,000 dols. was produced in that country. 1 total of precious metals was, therefore, 212,000,000 increase, as compared with the three preceding years.

**International Exhibitions.**—An Industrial Exhibition will be opened at Oplethorpe-park, Atlanta, G the 5th October, which will remain open until December. It was originally named the International Exposition, but it was subsequently decided to be textiles, and now all industries are to be held South American and International Exhibition to Buenos Ayres, will be opened on February 15, 1881 English merchants, at Shanghai, propose to have an International Exhibition to be held in that city in

## CANTOR LECTURES.

## THE ART OF LACE-MAKING.

By Alan S. Cole.\*

—DELIVERED MONDAY, APRIL 14, 1881.

*upon a material. Needlework upon separate Venetian needle-point lace. Needle-point lace. French needle-point lace-making English and Flemish needle-point lace.*

In my previous lecture I tried to show when the making arose, and by whom it was first. This evening I propose to deal with one special method of lace-making, and the kind in this method. Lace, as an ornamental arrangement of threads, has been reduced in various sorts of threads. We find gold and silver threads, of white, black, and silks, and of white threads, which are of linen or cotton. The white linen is that in the production of which the most artistic designs have been used. With this particular class of lace, I propose to deal. Broadly speaking, hand-made lace is a textile fabric perfectly distinct from a woven textile fabric. As a material is close, and patterns are made it by varying the interweavings of the threads by using variously-coloured threads. Hand-made lace is produced by looping, or twisting threads together. The loop, with a sewing needle, and the thread, the needle, is constantly at work, being looped around and between certain threads, which form the backbone of the lace wrought. Plaiting and twisting is done in several free and loose threads one after another, so that single threads are by turn in operation. This latter method comes in reading pillow and bobbin-made lace, but this we shall deal in the next lecture. Now, when we are to consider the looped and ad work done with a needle, and hence needle-point lace. Needle-point and pillow-lace, two chief divisions of the hand-made lace, without some acquaintanceship with the character of their productions, it would be difficult to retain of their salient characteristics. It is, therefore, the difference between these two

classes of lace (pillow and needle-point) is often quite marked. For instance, one may compare a piece of Valenciennes pillow-lace with a piece of Venetian needle-point lace. The Valenciennes pillow lace is quite flat and thin in appearance, whilst the Venetian needle-point lace is marked by portions in relief and a sort of modelled appearance. (Figs. 1 and 2.) A similar difference would

FIG. 1.

Valenciennes pillow lace.

not be apparent if we compared the same piece of Valenciennes with a very delicate Venetian needle-point lace, called "point de Venise à réseau."

FIG. 2.

Venetian needle-point lace.

The variety of pattern which we should find in three such specimens could not even be taken as a guide to class of work, as respects needle-point and pillow-lace, since, in the halcyon days of lace-making, the same pattern might be worked by the needle and on the pillow.

III. Attention to the characteristics of workmanship in lace has often been too slightly paid by those who have otherwise shown themselves to be connoisseurs in the matter. The late Mrs. Bury Palliser, whose name is closely associated with

\* Of reproducing the illustrations is reserved.

the history of lace, not unfrequently had failed to acquaint herself with such characteristics. She described some needle-point lace as pillow-made lace and *vice versa*. It would be ungrateful on my part if I allowed you to infer from these remarks that I was not sensible of my indebtedness to Mrs. Palliser's "History of Lace." Her patient research was almost exclusively devoted to the exhumation and laborious accumulation of records about lace. In this respect chiefly her history of lace is a valuable volume of reference. I must repeat, however, that records and writings hardly seem to be a first source from which materials for forming an acquaintance with lace-making are to be drawn. The abundance of existing specimens of all sorts of lace invites our attention, and enables us to trace developments and phases of the art in its productions. When methods of workmanship and styles of design have impressed themselves upon us, then we may have recourse to records and writings, and fit together in as complete a way as we can, the evidences we have thus obtained. I will not say more on this matter, but proceed now to ask you to consider with me features of workmanship in needle-point laces.

IV. Without referring to any particular class of needle-point lace, it will be seen that a beginning must be made somewhere. The pattern governs this beginning. Say then we want to make a little square in lace. We first draw the form on a piece of paper or parchment. Parchment being less destructive is the best. Then lay upon the lines a thread which is fastened here and there to the parchment by stitches. Having completed this thread skeleton pattern, we begin to build a compact covering of white threads upon it, which we do in ordinary button-hole stitch, the result of which is that the skeleton outline becomes a well-marked figure. This is the very simplest form of needle-point lace. If we want to go a little further, and place, say, a pattern in the centre of the square, we should draw one pattern, and then outline it with thread, taking care to attach the lines of this addition to the main lines of the square, and then we proceed with one over-casting of button-hole stitches. There remains now the question how the pattern is to be taken off the parchment. This is easily done, by neatly cutting the stitches at the back of the parchment, which stitches you will remember were those which held the first skeleton outline down. The lace is thus released from the parchment, and the pattern is ready for use for another piece of lace. However, all that we have done is to produce a sort of geometric form of even lines, and this is virtually all that was done at the commencement of needle-point lace-making. Much depends, as you readily perceive, upon nice thread and careful patient working; the least scamping or putting a loop out of its order, takes away from the compactness of the work; and irregularity and loosely made lace condemns itself.

V. Before leaving the early and geometric stage of lace, as we have seen it, which, by the way, was called "*punto in aria*" (see Fig. 3), a term you will recollect from my first lecture, I think we may find it useful to glance at a few of the classes of white thread embroidery which existed before, and contemporary with "*punto in aria*." We have seen that the beginning of lace

is separate threads. This is quite reverse broidery, which requires a stuff as a found

FIG. 3.

"*Punto in aria*."—Geometric design, with an edging of and twisted threads.

VI. When the fashion of ornamenting white garments was getting up to its zenith, I devised methods of decoration other than the merely loading the surface of a stuff with broidery. A lightness was obtained by cutting bits of the stuff, or by punching series of little like the tailor bird. One of the more elaborate forms of this cutting-out work was 10th or Venetian "*reticella*," which is also called times "*tagliato*," or cut work. The design of this sort of work, difficult to distinguish from "*punto in aria*" done from similar patterns, is geometric. The principal lines are rectilinear; this arises from the fact that the cutting-out of the stuff generally followed the woof or the linen. These rectilinear lines consist of very narrow strips of linen, or three or four uncut threads, worked over with button stitches, just as our skeleton outline in "*punto in aria*" was secured. Between these lines a circular and radiating forms, which were like "*punto in aria*," and it is curious to find that, although the embroiderers of lace devised methods of inserting into places of linen such open ornamented work as done in

FIG. 4.

yet they seem to have been some little time they were able to work this sort of ornament to form a band or trimming, independently, as a foundation.

VII. Another cut or "*tagliato*" was with linen was of a very obviously a recter, as you see from the specimen here. This vandyked scroll is cut out of a strip of and is picked out with fine gold wire, along its edges. (Fig. 5.) The name "*in*

or cut work with leaves, was given to a kind of lace, and this has led to some ; as the term "cut" indicates a process

FIG. 5.

Vandyke of cut linen work.

thing to do with the making of lace like Fig. 2, which was, nevertheless, called "tagiami." Much as it may look like cut linen, the reliefs and ornaments embroidered upon the specimen of very elaborate lace-work, entirely by needle and thread upon a flat pattern, so that cutting has nothing to do with the shaping or ornamentation of the

Continuing with the white embroideries, we may look at a specimen of drawn work. Here we have another sort of work, from either of the cut works. The threads regulated the pattern to a well-curved scroll had to be containing approximately rendered in small. The back ground to such work appeared to be of a net of square meshes. This effect was produced by whipping fine thread around the threads of the stuff. Just the reverse work is the very well-known darning, of which there are many made imitations now. For this sort of rederio Vinciolo made many patterns, the earliest of which date from about the Italian name for the work was "punto" and the French "lassis" or "lasis." Venetians, or rather Venetians, preceded each in this sort of work, though each carried it to a degree of admirable perfection. I remember that in the South Kensington Exhibition of 1874, there was a most specimen of this darned work, a large tablecloth, or altar cloth, set with squares of upon a net ground, in which were representations of the zodiac and of the seasons. These were after designs by Vinciolo, as seen in such well preserved copies of his ; those belonging to Mr. Alfred Huth, kindly allowed me to consult his copies of It was particularly interesting in this design to notice the final squares, in one of which were the words, most carefully darned,

*Louant Dieu j'ai fini mon ouvrage*, "praising God I have finished my work," and in the other the name of the worker, "Suzanne Lescallez, 1595." The cloth, after the Exhibition, went back to France, and I don't know where it is, but it is so complete a specimen, that if by chance any one happens to meet with it, I hope they will make a careful note of its whereabouts. On a far smaller scale, and of altogether less artistic importance, are the few squares of "lasis" or darning, introduced into this cloth. (See Fig. 6.) Those appear to be reproductions of some

FIG. 6.

Corner of an embroidered linen with squares of "lasis" and "Reticella" inserted, and edged with twisted and plaited threads.

of the smaller designs by Vinciolo. This Vinciolo is an important personage in the history of lace. Besides the darning work, or "lasis," which is not lace, he popularised the taste in France for "points coupés," the French name for "reticella" and cut-work, and also for "punto in aria." He seems to have borrowed much from different sources, and it is interesting to compare his patterns with those done by C. Vecellio, a notable and rather later designer and writer about costume towards the end of the 16th century, and some relation to the great Titian, and with those done by a much-esteemed woman, named Isabetta Catanea Parasole, whose patterns were published in Rome about 1590 and early in the 17th century. No doubt Vinciolo owed much of his success to the patronage which Henry III. and Henry IV. of France and the ladies of the French Court accorded him, though, at the same time, we must not forget that he was a man of energy and refinement, as his books show. He is almost the only early pattern maker who attempts a description of how the patterns are to be worked. His descriptions, however, are more enthusiastic than instructive. They are given by him in verse, in what he calls a discourse upon "Lasis." His divine *chef d'œuvre* is not a matter of chance; it has been well considered and planned by number and measure. Before leaving the "lasis" or darning on net, I would observe that the name given to the net was "résail," and this name must be noted, since we find it, later on, applied to ground-works of meshes used in laces. You, all of you, know what netting is, and how simple an operation it is to

FIG. 7.

make one mesh. I will show you a few meshes done with the needle (see Fig. 7), and you will

then see the far greater complication of this work, as compared with netting, and yet the name "réseau" in France applies to both.

IX. We have now examined different sorts of embroidery on linen. (1) Work done by cutting holes into a linen foundation; (2) work done by cutting linen into shapes; (3) work done by drawing out threads, and so leaving a linen pattern; and (4) work done by darning a pattern into network. We have also seen specimens of the early geometric laces—the "punto in aria," or button-hole stitch work done upon a thread skeleton; and now I should like to show you a piece of mixed work, in which a little more than mere geometric form is displayed. (See Fig. 8.) The

FIG. 8.

Vandyked border of mixed work, the upper part of needle-point, the lower and dentated part of plaited and twisted threads.

upper part is all of needle-point work, whilst the lower is of plaited work. Some of this plaiting may, no doubt, have been done with a hooked needle. However this may be, I thought it useful to show this specimen, in order that you might not fancy that the whole of a single piece of early work was done in one method only. Patterns for lace like this are to be found, especially in Vecellio's books, about 1590 or 1600.

X. We will now look at a few specimens, from which I think we shall trace a freer sort of design, and, consequently, an increased display of ingenuity in workmanship. We have hitherto seen ornaments, more or less dependent in their construction upon squares and their diagonals. But the pattern-

FIG. 9.

Italian needle-point vandyke.

books of the end of the 16th century give us designs for scrolls, with the introduction of all kinds of odd figures to be worked in lace. The

specimen of this class (see Fig. 9.) dates, perhaps, from about 1580. I want you to notice the different details in the design touch one another at different points of contact. There are very little ties. Considerable parts are of flat-linen work, work which in this photograph looks like linen. It is composed of a series of closely-loops worked very much as shown in Fig. 4.

XI. In the specimen in Fig. 10, I

FIG. 10.

[Needle-point lace, showing use of ties or "brides"]

you to notice the numerous little ties which are used to hold the pattern together. These ties are called "brides." The design too of this is more vivacious than the simple rosettes and repetitions. In the centre we have a shield surmounted by a crown. Curves slope from each side of the shield to meet beneath a sort of fan pattern, from the centre of which grow a little *fleur de lys*. The vandykes which hang beneath, are repetitions of the device, and are terminated with little balls. Between the vandykes are small loops, which serve as loops for buttons, but I cannot say for what particular use this specimen was intended. From the character of the design I think the specimen is from about 1590 to 1590, and is Italian. It is, of course, a French or other imitation of Italian work.

XII. Very important work of this character was made, and amongst the threads gold threads were introduced. I find that Sir William Drake possesses a specimen as ever were wrought of this silver and gold thread needle-point lace. They are, I think, of early 17th century design and workmanship. Originally they came from Milan to which place they may have been taken by a wealthy person at the time when that city was a centre of considerable importance, notable for its independent and aristocratic prosperity.

XIII. In the succeeding examples, you notice a development of flowering stems and scrolls. A change of design had thus begun to take place at the end of the 16th and began of the 17th centuries. Here (in Fig. 11) you see too a greater use of the "brides" than we have previously noticed. Along the border the stems or scrolls is a little raised line. It is called the "cordonnet," a feature not absent in the fine gold and white flowered of Sir William Drake's. Parts of the pattern are drawn

f stitch. Instead of compact work every-  
should see little open works. In the centre  
the little blossoms there are wheels and

of tape lace combined with needlework.  
in pillow lace also used tape in a similar  
is little strip (see Fig. 12) may be Italian,

FIG. 13.

Tape lace worked with the needle.

lace was not only produced in Italy. This  
(see Fig. 13) may not unlikely be of  
workmanship. My reason for thinking it  
is the style of the flowers along the

borders, which appears in a lace (see Fig. 14) much  
liked by the Flemish in the first half of the 17th  
century. The points of resemblance lie in the

FIG. 14.

Flemish lace of the 17th century.

arrangement of the petals of the blossoms, which  
takes a fan shape.

XV. Before leaving the question of tape laces, it  
may be well to state that the weaving of tape seems  
to have been begun in Flanders, about the end of the  
16th century, or the beginning of the 17th. Tape,  
so far as I have been able to ascertain, did not  
come to be made in England until the 18th century,  
when, according to a note I have had from Messrs.  
Phillips, the well-known tape manufacturers at  
Manchester, their predecessors brought over, in  
the year 1747, two Dutchmen, of the name of  
Lanfort. Under the tuition of these Dutchmen,  
the people in the village where Messrs. Phillips  
have mills at the present time, learned how to  
weave tape in the loom. The start in England  
was up-hill work, because of Dutch competition.  
There were at least 1,000 looms at work in Holland  
before there was one in England. However, in  
about thirty years, the trade greatly developed,  
and, in the course of a half century later, several  
other tape looms were started. This was about  
1820. Since then the manufacture has increased.  
Before 1822, tape was made in cottages; but, in  
or about 1822, the idea of getting the workers and  
their looms under one roof had taken root, and  
mills were built. Then came steam power and  
water power for driving the looms, instead of  
human power. Effective work has been done with  
tape, in connection with the method of pillow-lace  
making. Work of this sort is sometimes called  
guipure. But guipure is a class of work totally  
distinct from this, and about guipure we shall  
hear something in the next lecture.

XVI. However, we must now return to needle-  
point laces. Up to the present we have arrived at  
scroll designs more or less flatly worked, held  
together by ties or "brides," enriched with little  
varieties of "fillings in" or "modes," and em-  
phasised with small raised lines or "cordonnets."  
All this sort of work was done upon a thread  
skeleton pattern just as the first needle-point  
laces were made. Fancy in design and work-  
manship, however, was now becoming quite  
vigorous. We enter a period, soon after the com-  
mencement of the 17th century, when lace  
workers produced beautiful solid looking

which is almost like fine 14th century Gothic tracery, carved in ivory. Its exquisitely worked relief carried recent admirers of it far away from the time when it was first produced. They tried to identify it with a needlework which an Italian poet, Firenzuola, a hundred of years before the existence of this relief-lace, described as "sculptured in relief." As the size of the altar-cloth, flounce, border, or collar seemed to demand, so did the lace-workers vary the size of their designs and work. For instance, a collar would be designed and worked as this one. (See Fig. 15.) The

FIG. 15.

Part of a collar of minute Venetian needle-point lace.

figure is not quite distinct, in showing the amazing delicacy of the relief work and its enrichment. Each of these little blossoms, actually about the size of sixpence or threepence, is a bouquet in itself of hundreds of the most finished lilliputian loops, finely worked in button-hole stitches. Again, for a border or an ornament to hang beneath the chin, we have specimens such as this (see Fig. 16),

FIG. 16.

Venetian needle-point lace.

and in this specimen the decorations worked upon the little ties should be noted; while, for a sort of collar, the ends of which spread flatly over the breast of some courtier or minister, say like Colbert, we have samples as shown in Fig. 2. In all these specimens is a rich expression of stately scroll design—varied fillings—in or "modes," "galleries," or successions of minute loops "picots" placed one above the other. This was the kind of splendid needle-point lace, exclusively originating, I think, from Venice in the 17th century, which the nobility and wealthy personages of the time wore, and of which vestments and altar-cloths were made for churches.

XVII. A contrast to this galaxy of lace is to be found in the needle-point of England during the 17th century. A specimen lies on the table, in which is shown various vandykes of English needle-point of the 17th century. Remarkable amongst these are two larger vandykes, which you will find the one, a figure of a man—the other, a woman, depicted in the costume of the 17th century. The way in which this work was done is similar to 17th century flat Venetian needle-point lace. Here is a specimen of the English (see Fig. 17.)

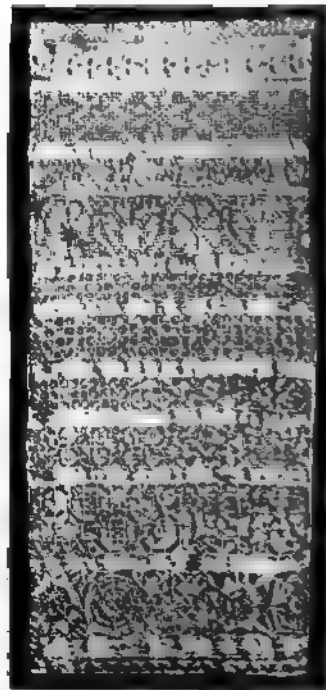

FIG. 17.

English needle-point lace.

XVIII. Scallops of "punto in aria," inserted "reticella," and of similar design, may also be seen in Westminster Abbey carved upon the tomb of

to a chalice. The little ties ornamental loops form a background of style of design is no longer dignified scroll, but consist of a cement of fragmentary details, in on of which clusters of picots is imilar style in using disconnected bservable in Messrs. Hayward's

efore quitting the long flowery you to observe the varieties of growth of which we had begun to 1, and I again refer you to the scroll work. (See Fig. 2.) At that new effects were being tried d workers, the best forms which these attempts were also preserved you will see that, although in design supplanted one another,

there were lingerings of old styles contemporaneously worked with new styles. And it is the consideration of incidents like this which I think must always puzzle connoisseurs of styles of ornaments in their attempt to fix a very precise date to a certain pattern. We may know that such and such a pattern may have been worked at a certain date, but we cannot fix with precision its first introduction, or its final appearance, neither can we be confident that a repetition of it may not be of very later date.

XXII. With the style of balanced arrangements of detached ornaments which is closely connected with the style known as Louis XIV., we find the first indications in lace of a groundwork of meshes made with a needle. (See Fig. 20). This

FIG. 20.

Needle-point lace with ground of fine meshes.

figure is rather indistinct, and does not show the ground of meshes clearly. Perhaps, however, the indications of it are sufficient to let me ask you to take my word for it that the ground is composed of meshes, which are in the main similar to those of Fig. 7.

XXIII. You will hence note how that we are getting into a period when grounds of meshes were being used. The daintiest of all Venetian needle-point laces, with fine grounds, is the "Point de Venise à réseau." This most delicate work was contemporary with soft pillow-made laces, which no doubt were intended to be its rival. In its production were combined the highest elaboration of design and workmanship, together with a thinness and beautiful softness of texture. It is one of the rarest of all laces. It marks a transition from preceding heavy to succeeding light laces. It followed the change which articles of costume, like collars and cuffs and trimmings, underwent from the 16th to 17th centuries.

XXIV. High-standing ruffs, like those worn by Queen Elizabeth, had been trimmed with "reticella" and geometric "punto in aria." But the vandykes expanded in size, and instead of shooting off from borders of the ruffs, became unmanageable for work.

remarkable "Point de Venise à réseau." The old vandykes had, in fact, disappeared, though their name, "dentelles," was retained for their successors, from which the dentated character was almost entirely extinguished.

XXV. We have now arrived at about 1660 to 1680, and this is an important date to remember in connection with the history of lace.

XXVI. A view of the situation might be stated to be, Venetians, at the end of their famous hundred and twenty years of work, to bring lace to a perfection, and other countries doing their utmost to acquire the art from them; some, like the Flemish, progressing slowly and naturally, following Venetian patterns upon the pillow; others, like the French, bent upon stepping by any means to a front rank.

XXVII. The desire of the French to be able to make fine lace was undoubtedly most strongly expressed in an edict dated 1660. Louis XIV.'s minister—Colbert—was the prime mover. He had taken stock of the increasing love of the French people for Venetian and Flemish laces. His love for the fine arts in all their branches, and his great energy, were principal elements in the framing and issue of this celebrated edict. Through it lace-making establishments were founded at Alençon, Quenoy, Arras, Remis, Sedan, Chateau Thierry, Loudun, and elsewhere. The State made a contribution of 36,000 francs in aid of the formation of a company to carry out the work. Instructions were included in the edict that the lacemakers should produce all sorts of thread-work—as much those done with the needle as those worked on a pillow or cushion, in the style of the points which were made at Venice, Genoa, and Ragusa, and other foreign countries. These French imitations were to be called "Points de France;" and although attempts have been made to identify certain laces as "points de France," I think, considering the variety of laces which were to be imitated, and the classification of them under the

'lavori d'aria' to perfection;" and Domenigo Contarini, jealous of the were evidently ensuing, to the p making in Venice, alludes to the "which the French can now do Thus, from 1660 to 1677, we hav French labour, under State prote systematically trained, by import structors, in the art of lace-makin

XXIX. The style of design adopted was certainly much more floral than was lighter, and more in accord w of texture which lace was devel Great attention was paid by ground-works, which, in respect comb "brides" (see Fig. 19), and (see Fig. 20), they distinctly of Venetian masters. Mrs. Bury P that French lace-makers could i imitate the true Venetian stitches, for points d'Alençon were planne meet this deficiency, but I think t specimens here before us will be s us that, however fresh a departure taken by the French in the matte cunning in doing delicate need became as great as that of thei Venetians. It is surprising, I thi people become if they have not fir the difference between design an The best ability in representing generally runs a risk of being coo the pattern, and not the workman be condemned; and very often pre of such cases occurs, when a well in spite of bad or inferior work itself, and is then held up as a go

XXX. To return, however, to works, and their particular early distinctive French needle-; will remember the regular hex of Venetian laces (see Fig. 19).

ntan and that of Point d'Alençon appears. 1.) The clearly defined honeycomb ground centre of the figure is Argentan (so called), ie cloudy ground, composed of fine meshes, Jençon ground. Judging from the pattern of spot, I think it is likely to be of the latter end of 17th century.

FIG. 21.

French needle-point lace.

XI. The variety of groundworks and fillings in Alençon laces is very remarkable. Large ones, like one which belongs to Mrs. Alfred on, are rich in all sorts of fantastic devices, ground, and of work. The underlying principle of stitchery is the button-hole stitch, worked in skeleton patterns of fine thread, and sometimes in chain. Here is another specimen of Alençon lace. The groundwork is composed of what is called "réseau rosacé." This "réseau rosacé" consists of little solid flat hexagons of button-hole stitch set in frames of hexagons. A special characteristic of the Point d'Alençon laces is the "cordonné" stitched "cordonné." In the Venetian lace the outlines are of a thread. You will notice this if you examine the actual specimens shown. To thoroughly enter into minutiae of fine lacework would, I am afraid, take too many considerations almost never-ending. I have been able to present to you this as a sort of connected chain of phases of needle-point lace-making. I might extend it further, and speak of the Brussels needle-point lace.

It is, however, more or less evident that English or Belgian, in the matter of needle-lace, imitated their neighbours the French, and no doubt they had imbibed a large amount of knowledge in the course of their far earlier intercourse with the Venetians.

XII. I would conclude my remarks this evening by saying that the basis of all needle-point lace is the button-hole stitch, and that the features which you have to detect in judging a needle-point lace from a pillow-made lace are in this button-hole stitch.

## MISCELLANEOUS.

### ORANGE CULTURE IN SYRIA.

Notes on orange culture in a recent consular report from Beyrout, are quoted in the *Times*, from which we learn that the two districts in which

oranges are the most plentiful are those of Jaffa and Sidon. The orange trade began to assume considerable proportions some 40 years ago, when the new government of Egypt took shape, and it is now one of the most profitable in the two towns above mentioned. Unfortunately the inhabitants, allured by first gains, commenced planting gardens, and expending money beyond their resources, the result of which has been that, in spite of all remunerations for small outlays, their improvidence has placed most of them in the power of money-lenders, who continue to advance at interest of 15 to 20 per cent. However, a company has lately been formed in Jaffa to negotiate loans with orange cultivators, and if its operations be carried on fairly, we may expect an extension of horticulture, with benefit alike to the company and the borrowers. At the present moment Jaffa possesses some 340 gardens, averaging from 2,000 to 2,500 trees in each. The crop of fruit from these may be put down at about 36,000,000. A garden costs from 40,000f. to 50,000f., and brings in 4,000f. to 6,000f. per annum. For several miles round Jaffa extends a fertile plain, on which water is always to be found at a depth of 40 ft. or 50 ft. With capital and enterprise much of this might be planted, and the orange trade doubled in a short time. The present system of irrigation is that of small wells, from which the water is drawn by mules; but experiments have proved that very little engineering skill would be required in order to turn the streams of the River Andjah, some four miles from the town, over the plain. The land near Jaffa would then be cheapened in proportion as the value of that freshly-watered rose. At present, unplanted land close to Jaffa, able to support 2,000 trees, is worth 2,000f. to 3,000f.; but at two or three hours' distance it will fetch only 5f. to 8f. a deunum. The export is carried on chiefly by sailing boats for Egypt and Constantinople, and by steamers for Russia, Trieste, and Marseilles. Exportation in cases is a comparatively recent introduction, which has given considerable impulse to business with Europe. The orange gardens of Sidon are cultivated on the same principle as those of Jaffa. An acre of land at Sidon is generally valued at from 6,000f. to 7,000f., and is capable of bringing in an income of about 800f. The exportation begins in September, and is at first almost exclusively directed to Russia, till the winter closes the Black Sea ports, when it is continued to Trieste and Egypt. European cargoes are packed in paper and close cases, the rest are sent in open crates. Each case contains some 300 oranges or lemons, and last year's export is reckoned at 20,000 cases, all of which fetched very high prices, especially lemons in Russia. The average prices are for 1,000 lemons 150 to 170 piastres; while for 1,250 oranges, reckoned as a trade 1,000, the cultivator receives 70 to 80 piastres.

## ESPARTO OR ALFA.

By C. G. Warrford Leek.

The celebrated German traveller, Dr. Gerhard Rohlfs, devotes a whole chapter of his new book, "Neue Beiträge zur Entdeckung und Erforschung Africa's," to the subject of "Esparto, and its Increasing Importance in European Commerce," from which the following notes are condensed:—

A portion of the Sahara, known to the French as *le petit désert*, comes within the influence of moisture-laden winds, and is clothed with vegetation. One of the most useful plants, covering almost the whole district, is *esparto* or *alfa* (*Macrorhiza* or *Stipa tenacissima*). Long known and locally utilised for mat-making, it is only within recent years that the true value of this plant, which needs neither care nor culture, and thrives with a minimum of moisture, has been recognised. It grows in thick bunches close together, presenting a scrubby appearance, and reaching a height of six to ten feet. The tenacity of its fibre constitutes its industrial value.

it is scarcely fitted for consumption as fodder. Indeed, Duvoyrier states that it has such a powerful constipative effect, that the shepherds of the desert edge drive their camels and sheep every third or fourth day to drink at mineral springs, in order to counteract the binding action of the esparto dist. Rohlf's himself noticed how soon the camels and sheep grew tired of grazing upon it.

The one word *PAPER* explains the whole importance of esparto. The day has long since passed when rags and similar stuff sufficed to supply the world's needs of paper. The moment has arrived when new sources of paper material must constantly be sought. This is easily explained when we reflect that the yearly consumption of paper by the four great cultured nations of the world stands thus:—England, 18½ lb. *per capita* of the population; America, 12 lb.; Germany, 10 lb.; France, 8½ lb. These figures are always on the increase. And though Russia takes only about 1 lb., and Austria 4½ lb., the amounts in both these countries double themselves with every generation.

No plant seems better adapted for paper-making than esparto. It may be regarded as an inexhaustible source of wealth, not only in Algeria, but for all northern Africa. Algeria already owes a portion of her railways to this plant. The section from Arzew to Saïda is approaching completion, and others are in progress. Some seven or eight million acres of esparto ground exist in Algeria alone.

Hitherto, the greater part of the esparto grown both in Spain and North Africa has gone to England, though the Americans are beginning to import direct from Africa. Up to the present, German paper-makers have not availed themselves of the use of this plant. England, in 1868, imported 95,828 tons—92,927 being from Spain, and the rest from Algeria. But Algeria rapidly attained greater importance, while Spain fell off. In 1874, England's imports were 119,188 tons—54,942 from Spain, and 37,516 from Algeria. Since 1870 other countries have contributed to the total. Tunis and Tripoli figure in 1871 with 11,579 tons, increased to 18,670 in 1874. Malta provided 3,261 tons in 1871, and 7,185 in 1874, not of its own production, but derived from Cyrenaica, and the so-called Libyan coast plateau.

The influence of other lands, Tunis, Tripoli, Cyrenaica, and perhaps the Libyan coast plateau, upon the Algerian and Spanish trade, has, especially of late years, caused a reduction in price. As, however, in most of these lands, robbery is still rife, Spain and Algeria will long continue to enjoy a practical monopoly. How strongly the rational conservation of this valuable plant is urged in France may be gathered from the following words of the journal, *L'Exploration* (1878, p. 166):—"As in France laws have been made against the felling and destruction of forests, so must the Colonial Government busy itself with the protection of this great staple of the high plateau, and not only severely punish the before-mentioned crimes (burning by the Arabs, and killing of the plants by careless gathering), but also fortify the esparto region against the constant encroachments of the sand of the Sahara. [Rohlf's characterises the latter as a groundless fear, the sand-dunes being, on the whole, stationary.] It must not be lost sight of that all Europe and America are dependent upon Algeria, and that, should the whole esparto district be carelessly left to greedy robbers, who care little for the public property, finally nothing will remain but a neglected waste, an unfruitful steppe." It is as well to observe that, firstly, Algeria possesses, at the utmost, not more than one-sixth of the esparto region, and, secondly, the same land will, when desired, grow excellent wine.

On the subject of adulteration and faulty packing, Dr. Rohlf's quotes at length from Noble's circular of 14th January, 1876.

The preceding remarks indicate what stress is laid upon the export of this plant to France, Great Britain, and the United States, while Germany remains outside.

Yet none will suppose that Germany is in superabundance of paper material. The 1 trade alone has of recent years a value of million marks (£500,000). It is therefore German merchants that they should have attention to this material. With this ob at all advisable to go to Algeria, nor to German merchants would find it difficult to ing in competition with the old English ho not the whole remainder of North Africa of speak of Morocco, where, especially south Ger, a wide stretch of country still remains on which esparto forms the chief veg esparto-grown portions of Tunis, Tripoli, the eastward-lying Libyan coast plateau, Alexandria, are absolutely without any r merco; as the natives tear up the espart branch, so is it carried to the shipping and sent into the market. Here is a field enterprise. Dr. Rohlf's suggests the pc establishing esparto paper factories in localities, and supposes that about half of would be available as fuel.

The remainder of the chapter deals wi trade generally, but the whole tenour of it the Germans to no longer remain passive as ful of the resources of North Africa: and D not likely to preach in vain to his countrym if these waving acres of esparto offer such documents to the astute and cautious Germ not merit even greater attention from Already our paper-makers have cause to tre future, since France has made such strides and if our merchants allow themselves to be by German rivals on neutral territory, we have to import all our paper from the Cu spite of all that Mr. Routledge is doing for s

## CORRESPONDENCE.

### AUSTRALIAN FRUIT FOR ENGL.

I note with interest the information in the 9th inst., page 778, that we may expect fruit kinds from Australia. No doubt apples, oranges can and will be shipped to advantage this country, because all these fruits ripen & plucked; but I think the writer in th and India is over sanguine as to first-class being able to stand the voyage, and to such good condition as to compete with his hot-house productions. Be that as it may, my of thirty years as a grape grower teaches me never ripen in the slightest degree after being but merely wither and shrivel, &c. I think growers are agreed on this point. If I am shall be glad to be corrected. JAMES I

44, Spring-gardens, Manchester, 10th September, 1881

## GENERAL NOTES.

Agriculture in Victoria.—From the lately agricultural statistics of the Colony of Victoria in 1880-81, it appears that while in 1872 the area was 284,609 acres, under oats 178,944 acres, and 39,064 acres, and under hay 100,890 acres, the 1881, have increased under wheat to 576,416; decreased under oats to 188,916 acres, and less potatoes to 44,778 acres, and under hay to 900 The average produce per acre is considerably less than it was in 1872. In the latter year, the p 18-46 bushels of wheat, 10-78 bushels of oats, 5 potatoes, and 1-40 tons of hay. In 1881, the yield 8-86 bushels of wheat, 17-61 bushels of oats, 8 potatoes, and 1-02 tons of hay.

## OF THE SOCIETY OF ARTS.

No. 1,505. Vol. XXIX.

AY, SEPTEMBER 23, 1881.

For the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.O.

## EDINGS OF THE SOCIETY.

## CANTOR LECTURES.

## E ART OF LACE-MAKING.

By Alan S. Cole.\*

## III.—DELIVERED MAY 2ND, 1881.

*lace. Fibres and threads twisted and like rope, cord, twine, and braids. Fringes. Nets. Twisted thread-work in England in century. Plaited and twisted thread-work. rletti a Piombini. Simple work done on a manufacture of pins, gumpure, tape lace. s of scroll design. Grounds of meshes and icteristics of pillow laces. Italian, Flemish, rench, and English pillow lace.*

vening we are to consider the second hand-made lace, namely, pillow-made outgrowth of needle-point lace from done upon a foundation of stuff, then o or net of some sort, and at length leton pattern of threads, was, I hope, when we last met. The workmanship ent subject is quite different. Pillow- s built upon no substructure. It is a on of a pattern obtained by twisting ; threads. In the midst of the endless is of forms inspired by the sight of ll sorts, men, animals, flowers, leaves, ell as historic treatments in depicting hat which in primeval times claimed eing a pattern, now seems to relegate osition, which, if not considered to be e, is at least so humble as to pass fificance. Nevertheless, students of the rnament find much that is admirable ive in the simplest juxta-positings of rves. And in glancing at the use of ought in twisted and plaited threads t, of course, omit to note patterns of aracter.

noestry of laces made on the pillow may examples of primitive twistings and fibres and threads. In my first lecture a few such examples, and I hope you me if I again briefly remind you of y must be dissociated from works of They come into the class of rope, cord, naking. They are also nearly related rds, such as corset laces, sleeve laces, and to another branch of the same ely, narrow braids and tapes. Rope

\* of reproducing the illustrations is reserved.

making was known by the Egyptians in early times, and it appears probable, if not certain, that this manufacture was at a similar early date practised by Oriental people living much further west, as in the Hindoo Peninsula, and the immense Mongolian Continent. Amongst the peoples living there, the use of ropes and cords for purely utilitarian purposes was apparently followed by the manufacture of finer plaited and twisted cords and threads made of finer materials than rough fibres, such as coloured silks and metallic threads, wires, or delicate metal strips for decorative purposes. These came "in response to the first spiritual want of barbarous man," which, as Carlyle says, is decoration. At what date fringes were used it is perhaps impossible to say. Besides fringes, there seem to be coeval fine twisted threads upon which to string pearls, precious stones, and beads for personal adornment. As well as these we should not forget girdles or cinctures, which come to us from impenetrable epochs of religious myths. Nets of plaited, golden, and silken threads were worn by Grecian women. Fillets for binding their hair and foreheads were often narrow braids made with silken and metallic threads. Müller specifies the *diadema*, or fillet, which was placed among the hair, and was of equal breadth all round the head. The *tenia* was usually a broader fillet with two narrower ones at each end. Hercules and athletes are represented as wearing fillets composed of several *tenie* twisted together.

III. We saw an example of the art of plaiting and twisting cords together for borders, 800 years before Christ in Assyria. But the design of this was quite primitive. This primitiveness of design in twisting and plaiting threads appears to have continued for a long time. A different treatment of borders occurs upon the costume of certain Dacians who are depicted in the famous column, coming before the Emperor Trajan. (Fig. 1.) This is some 900 years later than the Assyrians.

FIG. 1.

Border from Dacian costumes, sculptures on Trajan's column (2nd century).

IV. Evidences of similar minor details of costume from the 2nd to the 12th century are scattered, and rather difficult to obtain. Something, however, can be gleaned from early Christian sculptures, frescos, and Mosaics, and from Byzantine works of art.

V. As I mentioned above, the term lace has long been applied to braids and such like. Gold braid especially, or as it is called, gold lace, is of ancient origin. Scandinavians and Danes apparently made such gold lace, remnants of which have been discovered buried in England.

VI. Before stockings came to be knitted, Romans and Barbarians used to encase their legs in strips of coarse, plaited, and woven material. These braids, as they might be called, were neatly plaited round the leg, from the knee to the ankle, as may be seen in the leg coverings on an early sculpture, probably of the 2nd century, if not earlier, of the "Good Shepherd."

VII. But I must not detain you with these instances of antique plaitings and twistings. We have to arrive at the use of finer twistings and plaitings as they may occur in decorating edges of costume. Refined and graceful little ornaments, consisting very much of small golden and silken threads plaited to form flattened cords, appear to have been common in the early 15th century. These little ornaments are frequently indicated along the borders of dresses and robes, such as those painted by Gentile da Fabriano, Fra Angelico (Figs. 2, 3,

FIG. 2.

A sketch, with indications of ornament along neck and cuffs. From a painting of Fra Angelico da Fiesole (14th and 15th century).

and 4), and Carlo Crivelli. These names particularly occur to me as I have noted examples of the ornamented work we are considering, in pictures by them.

FIG. 3.

Sketch of gold thread ornament, taken from a robe painted by C. Crivelli (15th century).

VIII. About the time of these artists, that is from 1387 to 1493, the wearing of linen garments develops. While women wore linen wound round

FIG. 4.

Sketch of veil, with border of open loops, taken from a painting by Botticelli (15th century).

their heads and necks, the ends falling over their shoulders, men wore scarcely anything which we should now recognise as a collar. A minute indication of an under-linen shirt appeared above the low cut jacket, plaited, or hanging loosely from the neck.

IX. In Holbein's time, which carries us into the

middle of the 16th century, the linen come into fashion, as may be seen from portraits. Along these early collars, as the first ruffs, a series of small loops, made of threads, was fastened. This sort of trim called "purling," and is similar to the loops shown upon the edge of a cloth. The purse of the carpenter, in the tales, is "purred with latoun." Latoun have been a sort of metal-twisted thread, purling, in its application to collars and was just the reverse of those Italian ornaments depicted by Crivelli and others, fastened on to the stuff of the dress, as in Figs. 2 and 3. The purl was open thread worked to the edge of a border, and was in use in the 15th century.

X. An interesting inventory of articles belonging to the Sforza family in 1493 contains of a pointed border made with "doili bobbins perhaps, or else knitting or hool." And this pointed border has been mentioned upon by different writers as being early. I think, however, we might correctly say it was a "purling." And if we may call it "purling" lace, then plaited and twisted belongs to the 15th century. It is, almost as much a lace as the border of Roman fringes.

XI. We need not perhaps here enter into etymological depths for the origin of lace. The meaning attaching to it is that of many other words undergone. Long before plaiting and twisting were applied to produce rich and varied designs, word lace had described the plaited threads in the manners above mentioned. As we have a remarkable instance in an MS. of the time of Henry VI. and Edward about 1471. Directions are given in making of lace Bascon, lace indented, dedered, lace covert, a brode lace, a row thynne lace, an open lace, lace for H such like. The MS. opens with an initial capital letter, in which is the figure of making these articles. But her implements those with which lace of ornamental quality the middle of the 16th century and on have been made. A clear description is given in combinations of two, threes, fours, five and fifteens were twisted and plaited. Instead of the well-known pillow, bobbins with which pillow lace is now made, was used. Each finger of a hand had a position assigned to it of serving as a peg. The MS. says that it shall be understood the first finger next the thumb shall be called A, B, and so on. According to the sort of two or braid which had to be made, so each of fingers, A, B, C, D, might be called upon like a reel, and to hold a "bowys," or a little ball of thread. Each ball might be of different colour from the other. A "thyn" might be made, with three threads, and fingers A, B, C would be required. A "ruff" stouter than the "thynne" lace might be made of service of four or more fingers. By occasioning the use of the thread from certain of indented lace or braid might be made a lace of more importance had to be made.

ad lace for "Hattys," the hands of an assistant are required. In the quaint language of the MS. tells us how we should take a fellow at him on our right or left hand. Thus the r would have an additional ten fingers or n the two hands of his assistant. For still mportant work, two assistants—one standing h side of the worker—would be required, twenty pegs or reels would come into use. cess like this, involving the employment of so people to produce an insignificant article ury, leads us to reflect upon the immense e which has been effected in four hundred not only in respect of the improved allot- of labour to willing hands, but also as ls the increased demand and consumption of l articles. The very idea of employing s as pegs, sounds ludicrous. The unfortunate r women who passed their time in holding r ten fingers, cannot have had as much ment out of their work as that which a con- l player at cat's cradle derives from his s. Indeed, according to Adam Smith's n upon the division of labour, they "must lost habits of exertion, and become as stupid gnorant as it is possible for human creatures me." Fortunately, however, in the little in of lace-making, conditions like this were last long.

f. The ingenuity of labour in producing ents in plaited and twisted cords, or laces, f curling them in open loops, and such like, linen collars and cuffs, was not lost upon ers of patterns. For soon after the publica- f designs in "reticella" and "punto in aria," id designs for "merletti a piombini" (Fig. 'Merletti' is the Italian for lace work, and

FIG. 5.

Fig. 5. The neck of a shirt, trimmed with "Merletti a Piombini." Italian. Late 18th century.

"piombini" means leaden bobbins. To work a like that in Fig. 5, it is apparent that ments other than fingers, or even a series of were necessary. And since traditional practice tes an origin of implements used, we are or less forced into an inquiry as to the mployment of the pillow, of bobbins, and of ll of which must have been somewhat used e Venetian patterns of "merletti a piombini" latter part of the 18th century. A cushion d, on which were fixed stuffs to be em- red by the needle, is possibly as early in use e open frame, and this latter was well e in mediæval times and even before them. a essential of pillow-lace making is the

means of holding in fixed places the little threads as they are being plaited and intercrossed according to the patterns required. This, I think, implies a necessity of pins of some sort. Now, before metal pins were in common use, we had rather the reverse of this process. Instead of the balls of thread being pendent, free to be thrown over the other, and thereby to twist and plait threads into patterns, we saw that balls or "bowys" of thread were, in the 15th century, placed upon fingers, and thus were kept in fixed position, the loose threads coming from them were plaited and twisted. But in pillow-lace making it is the loose threads from the bobbins which are fastened on to the pillow, and the bobbins, with their balls of threads, are constantly thrown about.

XIII. The process of making lace on the pillow is very roughly and briefly, as follows:—A pattern is first drawn upon a piece of paper or parchment. It is then fastened to the pillow. The pillow or cushion may vary in shape. Some lace-makers use a circular flattened pad, backed with a flat, circular board, in order that it may be placed upon a table. Other lace-makers use a well-stuffed round pillow or short bolster flattened at the ends, so that they may hold it between the knees. On the upper part of the pattern are fastened the ends of the threads from the bobbins. The bobbins thus hang over the pattern. The lace worker must be versed in the knowledge of where her fixed points are to be. These fixed points rule the way in which the plaiting and twisting shall follow the pattern. Into these points she puts her pins, as she comes up to them in the course of her work. They are, in lace of simple pattern even, so close together that a dense forest of them is soon massed into a very small compass. Without attempt- ing to convey an idea to you of the growth of such

FIG. 6.

Diagram showing six bobbins in use.

a forest, I will merely take a simple form, and endeavour to show you how, say a triangle, might be worked in pillow lace. These fixed points are

was made. A realisation of the pains and troubles expended and caused in producing it should increase our appreciation of it. We may regret the tremendous amount of labour. Still, whether we regret it or not, a piece of lace is a record—proper or improper, but, nevertheless, a record—of labour and time expended. And expenditure of labour and time, devoted either to the production of an ironclad or a bit of lace, seems, I think, worth that recognition which a knowledge of it forces upon us.

XV. You will have remembered the "purl" edges of plaited thread and silk, and the "merletti a piombini," in making which pins became necessary. Almost coincidently with the development of the "merletti a piombini," the rapid manufacture and use of metal pins seems to arise. A few years ago, the Commissioners of Patents published some abridgments of specifications of patents. And as regards pins, some interesting facts are stated, which are worth quoting:—"Pins formed of wire seem to have been unknown in England until about the middle of the 15th century, before which time they were larger than the present pins, and were made of boxwood, ivory, bone, and some few of metal." In Richard III.'s time, about 1483, there was a prohibitory statute against the importation of pins. Queen Catherine Howard is said to have imported them into England about fifty years later, and at this time Henry VIII. sanctioned an Act to regulate the "true making of pynnes." They were to be well pointed, with heads firmly soldered on to the stems. The price of them was not to be more than 6s. 8d. (or say, about 80s. of our money) per 1,000. Though used as dress fasteners, it is evident, from their then value, that pins cannot have been at all plentiful. The manufacture of them seems to have been of foreign origin, and when once started, it developed fairly rapidly. On the Continent, in Italy, Germany, Spain, and France, perhaps, pins became almost sufficiently

case, however, assuming that I drawn a pillow-lace maker at work not so conclusive on the matter designs by Parasole, published a 16th century. On these is a numbers of leaden bobbins to be patterns. Some require 18, other bobbins. Fig. 5 supplies us with a sort of plaited and twisted thread—we are considering.

XVII. Judging from some specimens of nearly similar work, I think the plaited lines in it were plait lengths. When a sufficient set worked, then the lengths of these be wound round a sort of bobbin. a few other bobbins containing threads, a number like 12 or 16 be would probably suffice for work without a multitude of small conjecture is to some extent corroborated in which we can trace a plaited fine cords. The quest somewhat involved, and without my ideas as to such a method of work observe that four or five plaited combination would be but a de "purling," which was done with cords interplaited.

XVIII. Before entering into white thread laces of maturer like to make one or two remarks done with stiffened cords or in some respects allies itself with work. This ornamentation in itself to be earlier, *quâ* importance of plaited and twisted thread-work under the name of "guipure," with gimp. Gimp is a small cord whipping round a narrow strip a small bundle of threads, or a of silk or flax, and sometimes li

reasonably called "guipures," perhaps, greater portion of the gold laces extant in the manner of 17th century pillow-lace, and are not therefore, as the true is, dependent upon the ductile of gimp or wire for retaining their

work here that it looks almost as though linen had been used, and from it had out the various forms. However, all ed and twisted thread-work done upon Somewhat similar to this in respect of he *passements au fuseau* used in France y 17th century.

u will, in the two recent specimens, have hat the flat portions resemble narrow tapes. Here is another specimen in it might be called a tape treatment is rent (Fig. 9). We have, therefore, soon period in early twisted and plaited s-making, when means had been r rendering broad and narrow forms, avy lines. In my last lecture I referred loyment of tape for making ornamental ace. A specimen of tape lace, with a meshes, lies on the table.

he art of pillow-lace making was not confined to geometrical patterns as

was that of needle-point lace-making. Curved forms, almost at the outset of pillow-lace making, seemed to have been found as easy of execu-

FIG. 9.

Flemish pillow lace. 17th century.

tion. One reason for this, no doubt, is that the twisted and plaited work was, as we have seen, not constrained by a foundation of any kind. The plaitings and twistings gave the workers a greater freedom in reproducing designs. They could be intertwisted between the fixed points of the pattern with comparative facility, whereas, as we remember, the first needle-point lace workers began their lace with a framework of rectilinear lines. Still the pillow-lace worker did not in the matter of pattern proceed altogether faster than the lace worker with a needle. They virtually kept an even pace side by side. If anything, the pillow workers seem to owe more to the designers of patterns for needle-point lace, than otherwise.

XXII. About the early 17th century, important designs for plaited and twisted thread-work were produced. Of such I have a specimen to show you. It is a bed-cover, about 4 ft. 5 in. square. Fig. 10 shows a quarter of the design. The

FIG. 10.

Corner of a bed cover of pillow-made work. 17th century. Flemish.

design is chiefly composed of double-headed German eagles, surmounted by a Germanesque crown, and of insignia of the order of the Golden

Fleece. In the South Kensington Museum it is described as being made of "tape guipure." But this clearly is a misnomer. There is no guip in it; neither is there tape in the accepted sense of the word. Although no doubt made in separate portions, afterwards fitted and fastened together, the whole was plaited on the pillow. A revised edition of the catalogue of the lace collections at South Kensington will, I hope, shortly correct the errors I have pointed out. But there is another question of interest attaching to the existing description of this fine bed-cover. It was bought by the Kensington Museum from Mr. J. C. Robinson, who had acquired it in Spain. Its proprietor, a member of a noble family, had a history that it was of Spanish workmanship, and had belonged to Philip IV. of Spain. Decorated bed-covers were in the time of that king much affected by wealthy Spaniards. But this fact, and the legend, have not convinced me that it is of Spanish workmanship. Because Frenchmen like Stilton cheese, and because we can buy good Stiltons at Chevet's, in the Palais Royal, we don't decide that Stiltons are made in France. In my first lecture I quoted incidents strongly tending to show that Spain had never been a country of importance in the making of lace—at least, at so early a date as that of this bed-cover. Spain published no lace pattern books. Her archives are replete with records of imported laces. She appears to me to have been as a great political and commercial power, unlike artistic and industrious Italy and Flanders. She may have been more like France, though perhaps less artistic; and France, even in the early 17th century, had little prestige in making laces. France later on acquired a renown, when she, or rather her King and Minister, established lace-making centres. I have not yet found out that Spain took analogous steps towards promoting the art of lace-making. Indeed, as times went on, her political and commercial power declined with apparently no immediate compensating resurrection of artistic industry. Now, Flanders and Spain, during the 16th and part of the 17th centuries, were under one Government. From Flanders, or as they are called Spanish Flanders, Spain imported most of the laces she wanted. Looking to the excellent completeness of this bed-cover, it seems to me to have internal evidence of being the work of Flemish lace-makers. Had it been of Spanish workmanship we should surely have had other specimens more peculiarly Spanish. And we might have expected to have heard of distinct Spanish laces, just as we have Points d'Alençon from France, Valenciennes, Mechlin, and Brussels laces from Flanders, and Honiton from England.

XXIII. For reasons slightly like these I have given in respect of Spain, not having been a lace-making country of importance, I am disinclined to believe in the well-known record, that a native of Nuremberg, Barbara Uttmann, invented in 1561, pillow-lace making. Her tomb in the churchyard at Annaberg, is a construction apparently of the present century. The people who erected it have inscribed upon it, "Here lies Barbara Uttmann, died 14th January, 1575, whose invention of lace in the year 1561 made her the benefactress of the Hartz Mountains." The sort of work which she is said to have made and taught to

the people was a species of knitting. She assisted in this by certain refugees from Padua. It is quite possible that she may have made sort of purling or even little bordering insertions like the "merletti a piombini" of the Venetians. But since the Venetians direct influenced the Flemish, Barbara Uttmann's sort of Flemish work can, I think, hardly be called invention. I mention this point in connection with German laces, which by the way have not acquired any artistic reputation, since an idea seems to have got about that Barbara Uttmann was an inventor. Early Flemish edgings are similar to the Venetian "merletti a piombini."

XXIV. We need perhaps trace the development of "brides" or ties and other details in pillow-making. The history of them would be similar to that I gave in respect of needle-point work.

XXV. As I have before remarked, deep pillow lace very much followed that in respect of point; and this we may see by comparing the two specimens (Fig. 11 and 12). In both

FIG. 11.

Venetian needle-point lace.

specimens we have the scrolls held together by ties. The ties are ornamented with little "piquets," loops, and fillings-in, or "modes," are noticed in both. In the pillow lace (Fig. 12), however,

FIG. 12.

Silk-cum-wool lace. 17th century

there are no such raised masses as those of our button-hole stitched work which we saw in the needle-point specimen. The general appearance of this specimen is quite according to a piece of Venetian scroll pattern, although it is flatly well. Much of this scroll work, sometimes with ties, sometimes with grounds of meshes, was done on the pillow, both in Italy and Flanders. The

men I showed you may, perhaps, be Italian. However, is a specimen (Fig. 13) presumed Flemish. A great deal of this sort of lace

FIG. 13.

bone lace, "à brides." Flemish. 17th century. Sometimes called "Point d'Angleterre."

imported into England in the middle of the century, and went under the name of "Point d'Angleterre."

VI. The real English lace of this time commonly known as bone lace, and was not so-called because it was made with bobbins. It was a lineal descendant of "purling" of Chaucer's time, and the twisted thread trimming to Queen Elizabeth's ruff. We may see border lace, fly bone lace, sculptured on the tomb of Doodridge, at Exeter, and upon other monuments of the 17th century elsewhere. Such was allied in style of make and design to Venetian "merletti a piombini." Bone is the name by which most English pillow lace during the 17th century was known. In the 18th century its manufacture was of sufficient importance to demand Parliamentary attention. We were influenced by Flemish pillow laces, and no doubt, doing our best to imitate them. Our English imitations were not fine and good enough to please noble and wealthy people, accordingly, as in other countries, obtained supplies of lace from abroad, and chiefly from France. Still it was thought wise to stimulate home-lace manufacture by stringently prohibiting importations of Flemish lace. To evade these import prohibitions, and to enable English lace to supply the country with the esteemed French laces, or as they had been called, "Points d'Angleterre," our manufacturers obtained the services of Flemish lace-makers, and induced some to settle in England. This took place about 1662, a date which closely corresponds with the time when France, by the help of Venetian employés, establishing her lace-making centres. France, therefore, more under paternal government than constitutional Parliamentary England, seems to have been the more successful of the two in obtaining celebrity for her newly introduced industry. "Points d'Alençon," I am sure, have always been more prized than Honiton

pillow lace. Bishop Berkeley in the early 18th century makes a remark upon the relative values set upon English, French, and Flemish laces. "How," he asks, "could France and Flanders have drawn so much money from other countries for figured silks, laces, and tapestry, if they had not had their Academies of Design." England has, however, now gone beyond France in the number of her Schools of Art, and through a solid progress of imperial and local co-operation she may soon be able to boast of a larger number of provincial museums, which in an important sense may become academies of design for the benefit of our manufactures.

XXVII. But we must return to our inquiries as to the development of pillow-lace making. We were particularly discussing pillow-made scroll designs held together by brides. Turning to pillow laces with grounds of small meshes, I have here a specimen of such work, and one in which a floral and more naturalistic treatment is noticeable (Fig. 14). Of about the same period—that is, I

FIG. 14.

Pillow-made lace, "à réseau." Flemish. 17th century.

think, near 1660—we have pillow laces in which other ornaments, such as heraldic devices and figures, were introduced. This (Fig. 15) is, perhaps, an Italian pillow lace of this period.

FIG. 15.

Pillow lace, with ground of meshes. Italian or Flemish. 17th century.

XXVIII. On the table are examples of Italian pillow lace, with a scroll pattern of conventional drawing, done with a ground of meshes. I am afraid that time will not allow me to trace the development of the various platings used at different lace-making centres for the meshed grounds or réseaux. Generally speaking, I do not think that these réseaux came to be made before the

17th century. The Flemish makers appear to have excelled in producing them; and there are three important classes of them which I will now proceed to show you. We may take the Mechlin first. Mechlin, as a lace-making centre, dates from early in the 17th century, at least. Here are two specimens of characteristic Mechlin laces; the one with a close design, in which appear boys blowing horns, and carrying bows and arrows, is in the style of Louis Quatorze ornament, while the other, with a ground sprinkled with little roses, is some 70 or 80 years later. A feature in Mechlin lace is the thread or *cordonné* which outlines the pattern; and another is the particular plaiting of the threads forming the meshes (see Fig. 16). When a

FIG. 16.

Enlargement of meshes in Mechlin lace grounds, showing the two plaited and four-twisted sides in each hexagonal mesh.

*cordonné* and this sort of mesh appear in a pillow-made lace, it is safe to consider the lace to be of Mechlin manufacture.

XXIX. The second of the important pillow laces is the Valenciennes. I will show you the meshes first of all. You here observe that the threads composing the sides of the mesh are plaited (see Fig. 17). No sides, as in the Mechlin

FIG. 17.

Enlargement of meshes in Valenciennes laces, showing the plaiting for all sides of the mesh.

meshes, are merely of twisted threads. No outlining thread or *cordonné* is used in Valenciennes lace. The pattern is flat, as you see it in this specimen of late 17th century. (Fig. 18.) This Fig. 19a is a specimen of later date, after the middle of the 18th century, when the patterns for lace consisted of flowers and buds sprinkled upon the ground, as we saw it, not only in the Mechlin lace, but also, during our last lecture, in designs for Point d'Alençon. The second specimen 19b might be called a piece of "Fausse Valenciennes." The work is less regular, and the meshes are differently

plaited. The third specimen, 19c, is a piece of century Valenciennes lace, made probably in France and is a much more wiry and less soft-

FIG. 18.

Valenciennes pillow lace.

lace than the old "Vraie Valenciennes" of the 17th century. An interesting example of a French done in the style of Valenciennes, with ill-

French.

Pillow lace.  
Valenciennes  
Made in France.

Scripture figures and legends, lies on the ground. There are indications that the date of its origin was about the first ten years of the 18th century.

XXX. Now a third important pillow lace is the Brussels. In Brussels laces we have all sorts of designs. Some are placed on the work of brides, others upon meshes. The pattern of the meshes of Brussels lace is different from that of either Mechlin or Valenciennes (see Fig. 20). The plaited side of a Brussels mesh is long, that of a Mechlin mesh, otherwise these two sorts of meshes are much alike. But a distinctive mark of Brussels pillow lace

plaited *cordonné* or edging which marks the patterns. This you might notice in this specimen (Fig. 21a). This piece dates from about

FIG. 20.

enlargement of mesh of Brussels ground, showing the four-twisted and two-plaited sides in each mesh.

the commencement of the 18th century, and the pattern is remarkable as being a pillow-lace rendering of an Alençon design. The second specimen (Fig. 21b) is of the same period. It is a mixture

FIG. 21.

Pillow lace.  
Brussels.  
18th century.

Needlepoint  
and pillow  
lace.  
Brussels,  
18th century.

needle-point and pillow lace. The details are worked with a needle and the ground is of pillow lace. The two specimens shown in Fig. 22 are variations of lappets. Fig. 22a is again an example of an adaptation of a Point d'Alençon pattern rendered in pillow lace. The rough indications of

the variety of devices introduced into this lappet do poor justice to the extremely elegant manner in which the threads themselves have been plaited to represent the forms of flowers, birds, variegated

FIG. 22a.

FIG. 22b.

Lappets of pillow-made lace. Brussels. 18th century.

“modes,” &c., actually shown in the original lace. The second lappet (Fig. 22b) is of close floral design, and this close arrangement of flowers and leaves, broken by small interspersed mesh grounds, has been considered to be a mark of early Devonshire lace. But the workmanship is precisely like the Brussels lace, and I am inclined to assign to such piece a Brussels rather than a Devonshire origin.

XXXI. Of the various methods used by Brussels lace-workers in executing portions separately, of bringing them and fixing them together to form a whole piece, as well as of the many combinations of needle-point and pillow-lace making, I am sorry not to be able now to speak. Such details would, if justly treated, supply matter enough for a separate lecture. The specimens upon the table are a small index of the variety of patterns worked by the Mechlin, Valenciennes, and Brussels pillow-lace makers, and some of them are, as you will see, of beautiful finish in workmanship, as well as of intricate design.

XXXII. My object this evening has been to place before you a summary of incidents respecting lace made on the pillow, and I hope I have to some extent shown you that it is a branch of the art of lace-making originating from a source different from that of needle-point lace-making, and yet, in the progress of its design and pattern growth, becoming much allied with that of needle-point lace.

## MISCELLANEOUS.

### ON A NEW SCREW GAUGE FOR ELECTRICAL APPARATUS.\*

By William Henry Preece, F.R.S.

It is very desirable to establish a gauge for the manufacture of various small screws used in the construction of telegraphic and electrical apparatus. Sir Joseph Whitworth, in England, and the Franklin Institute in America, have done this for the bolts and screws used in mill-work and engineering generally, but no one has extended either system to the finer work used in those numerous practical applications of electricity that are

\* Read before the British Association, at York, September 1880.

now becoming so important. Gauges and screw-plates are now as numerous as the makers engaged in the trade. Nettlefold's sizes of screws are, perhaps, those best known, but they are worked to a special gauge, starting from a diameter of 0.5 inch, which is numbered 32, and which has no known relation to any other gauge used in telegraphy. Whitworth's standard gauge for watch and instrument makers has not yet been adopted. The microscopical gauge is confined entirely to microscopes. There is, in fact, no fixed pitch, no form of thread, no recognised number of threads per inch, no gauge based on practice and experience. Hence interchangeability for repairs is impossible, and the difficulty of applying for materials from abroad becomes very great. Screws are now generally supplied as "per pattern."

Sir Joseph Whitworth has remedied these defects in the larger forms of machinery, and, at the present moment, there is not a ship in her Majesty's Navy which is not supplied with the same screws and the same threads. Many large engineering works, such as those at Crewe, are in the same happy condition. Sir Joseph Whitworth carried his proposed standards for taps and dies to 100 inch diameter, having 48 threads per inch, but his gauge has not come into general use for sizes less than 250 inch diameter. I have placed myself in communication with most of the principal electrical apparatus manufacturers in England, and they have not only expressed their willingness to accept a well-conducted gauge, but have concurred in the view I have indicated of the present unsatisfactory condition of the question.

It fortunately happens that, from the point where Sir Joseph Whitworth and the Franklin Institute start in one direction, we can move in the opposite direction, so that, not only can the two gauges be made continuous, but though necessarily different in their applications, they can really be made uniform in their character. Indeed, the Whitworth gauge might itself, with slight modification, be extended.

It is only necessary for us to consider angular threads; square threads do not enter in such small work.

The Whitworth gauge specifies that the pitch of angular threads shall be equal to the depth which involves an angle of  $55^\circ$ , and that the top and bottom shall be rounded off to  $\frac{1}{4}$ th of the depth.

Screws of a diameter of  $\frac{1}{2}$  in. (or No. A in the B.W.G.) have twenty threads to the inch. This is the starting point of the American gauge, and both deal with increasing diameters. I propose to start from the same point, but to work in the opposite direction, dealing with diminishing diameters. Thus my starting point is of the new No. 4 centimetre gauge, 261 in. diameter, having twenty threads to the inch.

The exchange of apparatus between this and Continental countries is now so general, that the adoption of the French decimal metrical system is well worth serious consideration. This is felt so much that in nearly every table of wire gauges the dimensions both in parts of inches and metres are given. The adoption of the metre as the unit length would secure adoption of the gauge abroad. The use of the inch as a unit leaves us in that singular insular position, to which Sir William Thomson pointedly referred in Section A. the other day.

There are two dimensions besides the form and nomenclature to be considered, viz., the diameter of the screw and the number of threads per unit length. I suggest that the nomenclature be that of the wire gauge. The form I again refer to.

For the first dimension we might adopt a special number, as is done in the trade now, or we may take the same number for the screw and its diameter in *mils* or in millimetres, or, as I propose, we should adopt the new centimetre gauge recommended for adoption by the committee of the Society of Telegraph Engineers (December, 1879).

For the second dimension I propose to take the 6th

multiple of the number of the screw in the centimetre gauge as a factor. Thus No. 5 screw twenty-five threads to the inch, and its diameter .225 in. No. 8 screw will have forty threads to the inch, and its diameter will be .161 in., and so on, as the attached table, which embraces nearly all now in use. In all other gauges the number per inch is perfectly arbitrary. In fact, at present with the same gauge and the same kind of number of threads per inch varies.

Thus, if there is any value in my suggestion have a simple nomenclature and a fixed gauge that already adopted for wires and plates, remembered.

The attached diagram gives an idea of the of the thread recommended by me for consideration has been carefully prepared with existing the

due regard has been paid to the essential requirements of strength, durability, and friction, but, in the of some, the depth of the thread is too deep in proportion to the diameter of the screw. In the small screw for telegraphic and electrical purposes we need consider the difference of metals employed.

There can be no doubt that a recognised with a distinctive name, based on a simple and easily remembered, and supplied by house as that of Whitworth will soon take to be generally accepted, if stamped with the authority.

I submit that the subject be referred to a committee of this Section for consideration and examination that a new gauge may be recommended for a with all the authority of the British Association

Patents in Turkey.—General Patent-laws lately passed and promulgated in Turkey on The Turkish Patent-law is substantially a copy of and German systems. Any person may take a deposit of drawings and specifications. Longest patent fifteen years; annual tax, 18 dollars. It must be worked within two years from the date of The penalties for infringement and the procedure same as in European countries. In Liberia it must be the inventor, or must have lawfully invention from the inventor. Drawings and of must be furnished. The Government fee is 50 \$ invention must be worked within three years after of the patent.

## CANTOR LECTURES.

## THE ART OF LACE-MAKING.\*

By Alan S. Cole.

LECTURE IV.—DELIVERED MAY 9TH, 1881.

*as to styles of design in hand-made lace. Traditional patterns. Sketch of the development of lace for knitting and weaving threads to imitate differences between machine and hand-made lace. Modern hand-laces at Burano, Bruges, &c.*

On this evening, in my concluding lecture, I propose to take a passing survey of a few of the principal features in the history of the art of lace-making, to which I have called attention.

In tracing the history of the two great classes of lace-making by hand, needle-point and pillow-lace, I have sought to establish a gradual development of the art, rather than to insulate it by itself, and regard it as some freak of handicraft of unaccountable spontaneous birth.

Needle-point lace-making is distinctly a branch of embroidery; pillow-lace-making, a lineal descendant of plaited thread-work and fringes. Both owe such fame as they have acquired to the taste and variety of form imported to their process by the genius of designers of patterns. Lace artists considered free threads (looped, and twisted) as a fitting vehicle for representation of patterns, a higher career for the treatment of looping, plaiting, and twisting combined. This career shows first signs of development in Venice early in the 16th century. From fancy, fashion, imitation, and other such extraneous influences, spread the newly-developed thread-work to other countries. In each country where the art happened to become important, the special circumstances of the various localities gave it some sort of character, either in a marked or a weak degree.

Thus, the laces of Flanders, in their first stages of growth linking themselves to those of old Venice, later on are entirely different in appearance from their ancestors. This is particularly so as regards the Valenciennes, Mechlin, Brussels pillow lace. French needle-point lace, on the other hand, has gained, as we have seen in the Point de France, a speciality in appearance which, with-

out the gradual steps by which we have traced them from the "Point de France," might be said to have no likeness to their antecedent Venetian parents. English laces, on the other hand, are not so markedly detached from the general family. On the whole, they closely resemble Brussels, Mechlin, and Valenciennes laces, though at the same time Honiton lace, with its prettinesses of floral devices, may claim to stand by itself. In respect of other countries, the methods of making lace are similar to those involved in one or other of the categories above specified. The designs of such laces are either direct imitations of older laces, or else are of so unmarked and general a character as to lose themselves in the primitiveness of design, which may be said to be the common property of all former lace-producing countries.

V. I have prepared a diagram to show, in a general manner, the periods of different styles of patterns you will observe black bands of varying size. The first one is intended to indicate the growth and in lace-making (Fig 1, p. 800). These extend from 1540 to the present time; and I have roughly divided them into seven epochs, some of them overlapping, preceding, and succeeding ones. Upon the diagram progress of needle-point lace-making; the second, that of pillow-lace making; and the third, that of machine-made lace.

VI. In respect of hand-work, I think needle-point lace developed itself sooner than pillow-made lace. But the difference in data is possibly so slight as not to be worth close inquiry. Needle-point, at starting, took the stronger growth of the two perhaps. It seems to have reached a climax from between 1650 to 1720. Then it declined, and from 1790 to the present time it seems to have preserved an even life. It is not of such strong life as that of either pillow-made or machine-made lace. As regards pillow lace, it appears to have expanded in vigour, as needle-point declined, so that its period of supremacy might be placed at from 1680 to 1780. From 1790 to about 1850 the annual quantity of pillow-made lace became smaller perhaps than formerly, but soon it revived, and now seems to be larger. As to machine lace, that may be said to have begun its life with the machine-making of nets about 1770, and in a hundred years to have become probably more than a hundred times as important in quantity as needle-point and pillow lace combined.

VII. We have discussed, principally in their respective classes, those laces which have celebrity for beauty of pattern, as well as for fineness of workmanship. And we have seen that these come from Venice, Alençon, Valenciennes, Mechlin, Brussels, and I think it would be unpatriotic if we did not add Honiton. But, now, we should give a share of attention to other less celebrated laces, and I will therefore show you a few specimens of them. Of German provincial laces—evolutions, as we may take them to be of Barbara Uttmann's 16th century work—there are two pieces, both from the district of the Erzgebirge (Fig 2, p. 801). Although made recently, the patterns displayed in these laces might almost be of any date. They are, evidently, traditional patterns, handed down through generations of lacemakers, without much modification since the time when they were first made, which was, probably, in the 17th century. The upper specimen, with its large circular device and

quaint plant form, is similar to some lace made in Holland. The lower is what would be called a sort of "torchon" lace. The principles of design in this are simple, the pattern consisting of various lozenge shapes. It is not unlike that used by the peasants of Dalecarlia, in Sweden, who, for some

hundred and fifty years, have made this a lace, only in coarser thread than that used by Germans.

VIII. Patterns, somewhat similar, have been by the inhabitants of the Island of Crete. T a large collection of Cretan laces at the

Kensington Museum. Little, if anything, is known of the origin of lace-making there. It has a like- ness in many respects to the quaint pillow laces of South Italy. Crete has been intimately connected with Venice, and very probably Cretans learnt the art of lace-making from Venetians and other

Italians. The workmanship displayed in Cretan laces is remarkable. The design and twist threads is almost as good as artistic lace-makers at Brussels and Mechlin. Cretan laces are chiefly of silk. The pattern of the majority of the samples at the South K

um are outlined with one, two, or three coloured silken threads, which form the of the lace. As a rule, the motives of a lace patterns are traceable to orderly

FIG. 2.

ment and balance of simple symmetrical etrical details, such as diamonds, triangles, polygonal figures. Sometimes the patterns r origin to untutored imitation of a or leaf. Here are two specimens of the ce (Fig 3, a b). I have specially selected

FIG. 3.

laces from South Italy (18th century), and from Crete, Early 19th century.

one of the more ambitious of the Cretan design, that in which we have a line of stately figures, holding hands, strongly suggestive of those delightful persons which are cut out of paper for infantile delectation. The specimen beneath is of silk. Lace, I believe, is no longer made in Crete. The specimen in which two birds appear, together with forms, the meaning of which I cannot elucidate, is of South Italian lace (Fig 3 c).

IX. From Italy we may cross Bohemia, and place ourselves in Central Russia. Pillow lace has been made there for over a hundred years, by peasants of different districts. Following in the wake of fashion of Western Europe, Russia, under Peter the Great, towards the end of the 17th century, took up with lace-making. A silk lace factory was then established, but no cultivated artistic spirit ever raised the productions of this factory to special distinction. The patterns now used by Russian lace-makers bear all the stamp of traditional provincial patterns used by different European peasantries. Lace is made in Russia in the districts of Belev, Volozda, Tulasan, and Mzensk. This scalloped border (Fig 4 a) is made in the Beler district. Its

FIG. 4.

Russian pillow lace. 19th century.

big meshed ground is plaited similarly to Italian and Valenciennes grounds. The border (Fig 4 b) with small vandyked edge reminds us of the style of German and Swedish "torchon" lace. It is also suggestive of a lace made a few years ago at Ripon, in Yorkshire.

X. Thus, over a great area in Europe, we may judge how lace-making of nearly uniform style of design has spread itself. It is a humble and rather precarious means of support for peasants, and in this condition it cannot be expected to rise to any status of artistic importance. Sometimes a little stimulus is given to the efforts of one set of peasants, sometimes to another, as for instance, at the present time, when fanciers of hand-made lace purchase in fairly considerable quantities trimmings and borders of Russian lace.

XI. From specimens, the origin of which is identified with various countries, we may pass to lace-makers themselves, their training to the

two instances above referred to. Threads used for lace are made in a manufactory distinct from the lace manufactory. A like arrangement exists in respect of hand-made laces, that is to say, that the lace-worker is not also her own spinner of thread, though three hundred years ago, the spinner of threads, with her distaff and wheel, would sit in the same room with the needle worker; but this association of two separate employments in time was broken up, and division of labour, a subject full of interest, and ultimately connected with the development of organisation in respect of manufactures, arose.

XIV. The present position of lace-workers does not appear to differ very materially from what it always has been, and some interesting facts concerning it have been kindly supplied by Mrs. Percy Smith, in regard to Belgian pillow-lace workers at Bruges. Lace there is made by children and by adults. The children begin work in convent-schools, when they are as young as five or six. They first make a small "torchon" lace, smaller and less elaborate than specimen in Fig. 4b (p. 801), but of that character of work, in which you will not observe any subtleties of "modes" or fillings-in, like those we saw in the fine specimens of Brussels lace exhibited last Monday. Many of the young Belgian generation of artisan children are thus, early in life, grounded in the art of lace-making. This grounding takes up a principal part of their school-time, for whilst two hours a day are given to reading, writing, and arithmetic, the remainder of the day is devoted to lace-making. In a few parish schools, which are distinct from convent schools, lace-making is taught, but in a lesser degree than in the convent schools.

XV. As regards the class of lace-making women, the work by them is done in their cottages in the town. In summer you may look down long and wide back streets of the town, and see hundreds of women in groups of three, four, and five outside their cottages plying their bobbins most industriously. In winter if you walked down such streets you

agent, under penalty of a heavy G which thus is a protection for design

XVII. Now, as regards the design, remember how much a good reader depends upon the skill of the printer, where the pins are to be twisting and plaiting proceed. In instructors usually undertake to print but for the other body of lace-makers is done (at least, in Bruges) almost one woman, whose renown as a printer such, that, at the present time, she which will take her eighteen months

XVIII. Coming now to thread workers, it is a curious fact that flax is grown in Belgium, the machinery into fine threads is done. The thread, when made, however to be a pure flax thread, for the admixture of cotton with it; and a measure of hardness to the lace quality which earlier laces, made spun thread, do not, fortunately, lace-makers have to use hand-spun obtain it from the town of Alost, spinners make the thread. This thread is used for the better quality needle-point lace, specimens of which table. Work of such sort is done to and its price, £12 to £15 per yard four or five inches, renders it scarce

XIX. I now wish to offer you a few styles of patterns used in the United Kingdom, laces of Buckinghamshire and Devon perhaps amongst English laces. I (5, p. 803), showing three sorts of Br lace. In the first one (a) we may not fillings in. This variety gives the lace to such specimens. It is a work, but an adaptation of "Me Kant," or sampler lace, sent round purchasers to show the variety of the lace-makers hammered to be

bled Honiton guipure, or pillow lace with is a distinguishing characteristic of this class English lace. Sometimes a costly specimen of Honiton lace is made for a special purpose, and

FIG. 5.

English pillow lace. 18th century.

, according to the requirements of the person may have ordered the work, the lace is made better care than usual. Of such works we have two important specimens, lent by Messrs. Ward and by Messrs. Howell and James.

XI. Although private enterprise and courtly patronage have assayed, and to an extent succeeded, to plant the art of lace-making in the United Kingdom, and although from time to time direct foreign influences have been infused into it, as by George Flemings in the 17th century, a practice of the higher ornamental phases of the art has never fairly and successfully rooted itself here. Where artistic lace-making had fairly developed in the later years of the 18th century, England has been gradually slipping away from Papal supremacy. Convents and monasteries, in which centres of fine art have ever been fostered, have disappeared from England, and no institutions so strict for artistic and disciplinary success succeeded to them. To a cause like this we might assign the failure of England to become a leading producer of lace. A Frenchman, who wrote in 1852 upon lace-making, gives, however, a different cause, which is amusing. Granting that if the product of all products, requiring care in its development, be lace, how, he asks, is it possible to find grace in England? Do you think proof of this, writes this Frenchman? Look,

then, at an Englishman walking; look at him when he makes a bow; look at him as he takes a seat, as he enters a room, as he hands a cup to anyone, and so forth. The conclusion clearly is that the Frenchman was right—we were awkward, we had no grace, and so were incapable of making good lace. But now, remembering that such observations were made thirty years ago, when England, "perfidious Albion," was in her final stage of perfidy towards France, it will not surprise us much to find a vast and admitted improvement in regard to much of our lace-work. In the matter of machine lace, a subject we shall shortly touch upon, we may boast of as good quality of design and workmanship as exists anywhere; while for our hand-made laces, the specimens of Honiton pillow lace and Irish needle-point lace are surely re-assuring to anyone who is doubtful of British powers in this art. At the same time, in speaking of this Irish needle-point lace, called "facet," I must tell you that the greater part, if not the whole of it, is produced in Irish convents. Of other Irish laces I may say that there are about eight so-called different sorts. But Limerick lace is a tambour embroidery, I think; Carrickmacross lace is a sort of cut muslin work; pearl tatting, or "Frivolite," is clearly neither genuine pillow nor needle-point lace, and the varieties of crotchet imitations do not of course belong to either of the two important branches of the art.

XXII. Some thirty odd years ago, Parliament voted money for the encouragement of normal schools for lace-making in Ireland. From causes which do not require discussion, the Governmental encouragement was withdrawn, after having existed for some ten years, and the schools are now closed.

XXIII. Lace is made by Irish peasants in their cottages and cabins. They work chiefly from traditional patterns. No inspection for instructive purposes, or for suggestion of new patterns is provided, save such as may be derived from the relations between lace-dealer and lace-maker. The peasants are left somewhat to their own devices, and so one does not look for much artistic work from them. The better Irish lace—lace which may rank with lace of the finer classes altogether—comes from the convents, where fine old patterns and well selected new designs can be re-produced.

XXIV. Returning once more to the Continent, we shall find, in France, Austria, and Italy, a considerable life in the making of lace by hand. It is a popular fancy to suppose that the art is dead. The patronage which the wealthy can and do accord to the art, stimulates the production of new works, and while such patronage is intelligently and discriminately extended, the art lives.

XXV. From Vienna come occasional specimens of needle-point lace-work. The extraordinarily fine collar of needle-point lace, a modern version of the raised Venetian Point of the 17th century, lent by Mrs. Alfred Morrison, was, I believe, made under the direction of a Viennese lace merchant, who employs Bohemian lace-makers. Putting aside the question of design, which in this over-elaborated collar has not the dignity of an Italian 17th century raised scroll point, you will see here an astounding combination of almost incredible minutiae, executed with a perfection of

finish which rivals that displayed in earlier work. Needle-point lace is also made in France, exceptionally, perhaps, but still sufficiently to show that what has been done can be done again.

XXVI. In Italy a new departure has been taken in the making of hand-made laces, at the Island of Burano, near Venice. "This island, in the 16th and 17th centuries, was one of the principal seats of the celebrated lace manufacture of the Venetian provinces. The formation of the school recently established there, and the revival of the art of lace-making in Burano, arose out of the great distress which, in 1872, overtook its inhabitants. The extraordinary severity of the winter of that year rendered it impossible for the poor fishermen, who form the population of the island, to follow their calling. So great was the distress at that time, that the fishermen and their families were reduced to a state bordering on starvation, and for their relief contributions were made by all classes in Italy, including the Pope and the King. This charitable movement resulted in the collection of a fund of money, which sufficed to relieve the immediate distress and leave a surplus applicable to the establishment of a local industry, which seems to be not unlikely to permanently increase the resources of the Burano population.

"Unfortunately, the industry at first fixed upon, namely, that of the making of fishermen's nets, gave no practical result, the fishermen being too poor to purchase the nets. It was then that a suggestion was made by Signor Fambris that an effort should be made to revive the ancient industry of lace-making. Princess Chigi-Giovanelli and Countess Andriana Marcello were asked to interest themselves in and to patronise a school for this purpose. To this application those ladies yielded a ready assent, and at a later period Queen Marguerite graciously consented to become (as her Majesty still is), the president of the institution.

"When Countess Marcello (who from that time has been the life and soul of the undertaking) began to occupy herself with the foundation of the school, she found an old woman in Burano, Cencia Scarpanile, who preserved the traditions of the art of lace-making, and continued, despite her seventy years and upwards, to make "Burano Point." As she, however, did not understand the method of teaching, the assistance was secured of Madame Anne Bellorio d'Este, a very skilful and intelligent woman, for some time mistress of the girls' school at Burano, who in her leisure hours took lessons in lace-making of Cencia Scarpanile, and imparted her knowledge to eight pupils, who, in consideration of a small payment, were induced to learn to make lace.

"As the number of scholars increased, Madame Bellorio occupied herself exclusively in teaching lace-making, which she has continued to do with surprising results. Under Madame Bellorio's tuition, the school, which in 1872 consisted of the eight pupils (who received a daily payment to induce them to attend), now numbers 320 workers, paid, not by the day, but according to the work each performs. In this way they are equitably dealt with, their gains depending on their individual skill and industry.

"In Burano everything is extremely cheap, and a humble abode capable of accommodating a small

family may be had for from 600 to 1,000 Italian lire. It is not a rare occurrence to find a young girl saving her earnings in the lace school, in order to purchase her little dwelling, that she may take it as a dower to her husband. Nearly all the young men of Burano seek their wives from among the lacewomen, and the parish priest reported last year facts which showed conclusively that the moral condition of the island, consequent on the establishment of the lace school, has improved to a very striking degree.

"The lace made in this school is no longer exclusively confined, as in the origin it was, to *Burano Point*, but laces of almost any design or model are now undertaken.

"In order the better to carry out the character of the different laces, the more apt and intelligent of those pupils whose task it is to trace out in thread the design to be worked, have the advantage of being educated by means of drawing lessons from professional artists.

"The 320 workwomen now employed are divided into seven sections, in order that each may continue in the same sort of work, and as far as possible, in the same class of lace. By this method each one becomes thoroughly proficient in her own special department, executes it with greater facility, earns consequently more, and the school on its part gets the work done better and cheaper (although of course cheapness must always be very relative)."

XXVII. Besides specimens of lace now made at Burano, on the table before us, I can show you two slides of the lace. The first (Fig. 6) is a needle-

FIG. 6.

[Needle-point lace. Burano. 19th century (1874).

point lace, "à brides," with a marked cordure. It is rather in the style of so-called *Argente* designs. The second (Fig. 7) is more in the style

FIG. 7.

Needle-point lace. Burano. 19th century (1874).

of 17th century Venetian needle-point lace, with ground of hexagonal "brides" with "picots."

We have now to consider machine-made lace. And in approaching this section of my lecture, I must tell you beforehand that it is difficult to attempt to give a short description of the process. Of course, if we had had to discuss the mechanism of man, why and how his mechanism permits the manufacture of lace, in the same way that we may discuss the lace-making machine, the human machine would be the more wonderful of the two. Still, whereas I have devoted two lectures to processes of making lace by hand, and now propose merely to give a portion of a lecture to lace-making by machinery, you will not suppose that this determines the relative importance between the two branches of lace-making by hand and by machinery.

Mr. William Felkin has written a considerable work upon the lace machine. He shows that it is very much from the art of knitting that we trace the origin of the machine for making lace. Knitted caps and hose date in England from the end of the 15th century at least; as various Acts of Parliament testify. Knitted stockings, however, possibly from the difficulty of forming the heels and feet, seem to have been later, for Henry VIII. is said to have had, for ordinary wear, cloth stockings, "except there came from Spain by chance a pair of silk stockings." Even as late as 1610, "so unfashionable were young gentlemen commoners," that George Radcliffe, writing from University College, Oxford, to his mother, asks for a green baize able-cloth, "of which, if too little for my table, will make a pair of warm stockings." But some 7 years previously to this, the town of Sheffield an claim the credit of having given from its trust funds 13s. 3d. to "William Lee, a poore scholler of Sheffield, towards the settyng him to the University of Chambridge and buyinge him bookes and furniture." This William Lee, who became a clergyman, was for some reasons expelled from his college (St. John's), where he held a fellowship. He appears to have married an innkeeper's daughter, and after the loss of his fellowship soon all into extreme poverty. In his distress to find

source of income, his inventive faculties were called into play. The only support for his wife and child appears to have been derived from the sale of hand-knitted stockings. Sitting constantly with his wife, the scholar often fixed his attention on her dexterous management of the needles. In course of time he invented a mechanical contrivance, by which stockings might be more quickly knitted than by the hands. This is generally accepted as the first stocking-loom. The news of this invention, which was at once recognised as a formidable rival to hand-work, soon spread, but the antipathy to it prevented its becoming successful in England. Queen Elizabeth regarded with contempt a man's invention of a mechanical weaver of stockings, and the Rev. William Lee's petition to her Majesty for Royal patronage passed unnoticed. From James I., Lee gained as little encouragement. He accordingly went to France, Henry IV. and his minister Sully warmly espoused his cause, and matters went prosperously with Lee until his death. It might from this be supposed that France remained in

solitary possession of this valuable invention, but Mr. Felkin tells us that Mr. James Lee, son of Rev. William Lee, soon after his father's death, determined to transplant the manufacture of knitted stockings by machines to England. He accordingly brought frames and experienced workmen to London, and started operations in Old-street-square. Upon this becoming known, a spirit of imitation seized different people. Stocking-knitting frames were set up in Nottingham. Venice, the old home of artistic lace-making, was almost foremost in striving to establish stocking-knitting factories, but her attempts in this direction, through lack of skilled workmen, who should replace plant as it was worn out, soon collapsed. England, however, rapidly developed the number of her stocking looms, and between 1670 and 1695, upwards of 400 such machines were exported to France, Flanders, Spain, Italy, and Sicily. The English Legislature about this time placed its veto upon such exportation. The manufacture in this country continued in great force. Charters were granted incorporating companies for the working of stocking machines, and Parliament was called upon to consider petitions from the various manufacturing centres. In 1758, Mr. Jedediah Strutt introduced a method of ribbing stockings as they were made, and the machine for so doing was called the Derby rib machine. Other modifications of the stocking machine followed. It was about this time that taste for lace ruled that meshed grounds lightly sprinkled with small ornaments should be the most fashionable laces. Hence fine meshed fabrics like net and tulle seem to have arisen. Manufacturers in London and Nottingham applied themselves to make lace net upon stocking frames, about 1770, and so far as plain nets were concerned, they were successful in producing looped net fabrics of perfect regularity. Early in the present century, Mr. Heathcoat, of Nottingham, invented a machine for making bobbin net. After him came Mr. John Leaver, whose lace-making machines and modifications and improvements of them, to which have been applied the apparatus of the celebrated Jacquard loom, are in use at the present time.

XXX. Broadly speaking, lace-making by machinery is more nearly like the pillow-lace making process than that of needle-point. The machine contrives to twist any desired threads around one another. In pillow-lace making, besides twisting, we have plaiting. This plaiting has not been reproduced by the majority of lace machines. Quite recently, however, a French machine, called the "Dentellière" has been invented to do plaiting. Time will not allow me to refer in detail to the "Dentellière," of which a description has been published in a journal, entitled *La Nature*, dated 3rd March, 1881. Whilst, as we shall see, the ordinary lace-making machine belongs to the family of weaving machines, the "Dentellière" more nearly resembles the pillow of a lace worker, with the threads arranged over the pillow. In general appearance it looks something like a large semi-circular framework of iron, with thousands of threads from the outer semi-circle converging to the centre, representing the table or pillow. Over this central table is the apparatus which holds the end threads

side by side, and which regulates the plaiting of them. The cost of producing lace in this manner is said to be greater than by hand.

XXXI. In respect now of the lace machine which is in common use, I would ask you to reflect, that the mechanism to obtain and regulate the motions of each thread is intricate, and represents the sum total of much scientific thought, and its application to guide practice over a long course of years. Of the number of threads worked by a Leaver's machine, like that described in the *Journal of the Society of Arts* (18th and 25th Sept., 1874), it may be sufficient to say that there may be some 8,880. Of course the pattern to be worked into lace governs the number of threads. To produce the pattern shown in the *Journal* above-mentioned, 48 bobbin or shuttle threads, and 100 beam or warp threads were employed for each piece of lace. Sixty pieces of lace were simultaneously wrought, and thus sixty times 148 threads were brought into operation. This gives a total of 8,880 threads. Now, each of these 8,880 threads had its own particular duty to perform, and I hope to be able to convey to you some slight notion of these duties.

XXXII. The threads in a Leaver's lace machine then, may be divided, as they are in the loom, into two sets, the one which we may call the warp or beam

of the weft threads. The warp thread is arranged in trays or frames beneath the above which, and between it and the cylinder twisting of the weft with the warp threads takes place. The supplies of the weft threads are contained in flattened reels or bobbins, which are shaped as to be conveniently passed between stretched warp threads. Each bobbin for 1 thread can contain about 120 yards of thread. The most ingenious mechanism, varying degrees of tension can be imparted to the warp threads. The bobbins of the weft threads,

FIG. 8.

Diagram showing action of a slack weft thread in connection with taut warp threads.

FIG. 9.

Diagram showing action of a taut weft thread in connection with slack warp threads.

threads, and the other the weft or shuttle threads. The ends of both sets of threads are fixed on a cylinder or lace beam, which corresponds in its use with the first row of pins on the pillow, in pillow-lace making. The supply of the threads, warp and weft, is held by reels or bobbins. The reels of the warp threads are different from those

Diagram of principal details in a lace-making machine.

pass like pendulums between the warp threads made to oscillate, and through this oscillation threads twist themselves, or become twisted by the warp threads. As the twistings take place the combs passing through both warp and weft

the twistings. Thus the ordinary edge lace may generally be detected crossed twisted threads. In it will not y plaiting, such as we find in pillow-made lace by the "Dentellière" machine. moreover, trace in machine lace any of button-hole-stitch work, as we needle-point work.

FIG. 11.

at the same time we should remember visting in both these cases arises from on of the movements of the two sets in this matter, namely, the movement to side of the beam or warp threads,

and the swinging or pendulum-like oscillations of the bobbin or weft threads between the warp threads.

FIG. 13.

Pillow-made lace. Mechlin. 19th century.

XXXIV. The diagram (Fig. 10, p. 806) represents a section of part of a lace machine, showing X, the

FIG. 14.

Machine-made imitation of Mechlin pillow lace.

time, are most subtle. They are closely related to the Jacquard system of pierced cards. The machine lace pattern-drafter has to know more of this mathematical calculation than of drawing lines and curves. His work consists, principally, of calculating how many holes shall be punched in a card, and of settling where each hole is to be punched. Each hole regulates the movement of a thread

XXXV. We may now look at a series of specimens of machine-made laces. The first specimen (Fig. 11) is that of a Flemish pillow-lace design of the early 18th century. In it you will notice the variegated appearance of the meshes of the ground. A thread, you see, outlines the pattern, which has a fine linen appearance. Now the manufacturer (see Fig. 12) has merely attempted to reproduce the pattern. His meshes are regular. No outlining thread marks the pattern, which, instead of being filmy, like linen or cambric, is ribbed. This specimen, recently made at Calais with a Leaver machine, which is worked upon the principles I have above mentioned. The cost of this machine lace is 1s. 2d. a yard, and the value of the original is £1 5s. per yard. The next specimen (Fig. 13, p. 807) is that of a piece of Mechlin pillow lace of the late 18th century. In this you will again observe the comparatively slack manner in which the threads in the ornament are twisted and intercrossed. Here is the mechanical counterfeit of this piece (Fig. 14). The ground is similar to wire netting, while the threads to imitate those slack twistings of the original are rigid and much more regular. This, too, was made at Calais. The value per yard of the hand-made lace is £1 10s., whilst that of the machine is 2s. 9d.

XXXVI. I have now a better example of machine imitation of Mechlin lace. Here is the original lace. The appearance of the thread, forming blossoms, which seem to be a kind of sunflower, a series of petals around a dark central disc, is similar in their looseness to those in the preceding specimen. Now, in the imitation produced by the machine, we have an ingenious twisting given to the threads of the ground, whereby, in lieu of the simple twisted

lace, the *cordonnets* in which is This specimen was made this year we have seen machine-made imitation of class of pillow lace, i.e., laces woven to the pattern. Now, however imitations of Valenciennes lace may remind ourselves of the early made Valenciennes.

XXXVIII. Here, now, in 1

FIG. 15.

Machine-made imitation of Valenciennes lace.

quality of machine-made Valenciennes at Calais, by machines similar to Nottingham. Another specimen in design, and woven with finer threads, is considered to be as good as the machine-made Valenciennes.

Here we have the machine imitation (Fig. 17), of the ribbed appearance of the close porch, sharp, clear, outlining thread, and the com-wiry tautness of the ground, and of the series, it is a wonderful piece of imitation.

FIG. 16.

Needle-point lace, "à réseau" 17th century.

How much further man's ingenuity may mechanize to produce works, delusive of handicraft, is a question not to be covered, if answered at all. For anyone to follow the history of the art of lace-

FIG. 17.

Machine imitation of Venetian needle-point lace, "à réseau."

in its literary aspect, there is plenty of to be travelled over. But as I said in an lecture, I do not think that this way of pro-

ceeding is as instructive as it is entertaining; and I doubt very much if any one adopting it would come

To know the age and pedigree,  
Of points of Flanders and Venice.

XLII. In the times of the Provence romance writers, French ladies as they worked sang "Chansons à toile." Italian poets have sung the praises of the needle, just as Taylor, our Elizabethan water poet, has lauded the "Needle's excellency." Some verses composed by Jacob Van Eyck, in the 17th century, upon the art of lace-making, and a French epic, entitled, the "Revolte des Passements," appeared about the same time. Pope, Evelyn, Swift, Congreve, and many other writers of the 18th century comment on passing fashions, and refer to laces then in vogue.

XLIII. One of the latest of English poets, who seems to have perceived that patience, perseverance, gentleness, should predominate in the character of a lacemaker, is Mr. Lewis Carroll, who has immortalized a beaver with the art. A "beaver that paced on the deck, or would set making lace in the bow," was a member of that notable band of personages who went out hunting a snark. But when, as the poet relates,

The Doots and the Broker were sharpening a spade,  
Each working the grindstone in turn,  
The Beaver went on making lace and displayed  
No interest in the concern.

XLIV. The Barrister, another of the hunting party,

Tried to appeal to its pride,  
And vainly proceeded to cite—  
A number of cases, in which making laces,  
Had been proved an infringement of right;  
But the Barrister, wearied of proving in vain  
That the Beaver's lace-making was wrong—

soon fell asleep, and leaving him in that condition, I will conclude without making further quotations from this strange poem, which may not enlighten us much upon the art of lace-making. As it mellows with time, perhaps it may fall into its place as a stepping-stone in the literary history of lace-making.

XLV. It has been a privilege and pleasure to me to have been permitted to deliver this course of lectures upon the art of lace-making. In offering you my thanks for your forbearance with my shortcomings, as well as for the kind and appreciative attention you have evinced, I can but say that any dreariness which has attended my own personal efforts has, I hope, been relieved to some extent by the excellent illustrations furnished for our instruction and diversion by the authorities of the South Kensington Museum, Captain Abney, F.R.S., Sir William Drake, Mrs. Robert Goff, Mrs. Alfred Morrison, Mrs. Enthoven, Messrs. Hayward, and Messrs. Howell and James.

## MISCELLANEOUS.

### THE SOCIETY OF ARTS' PATENT BILL.\*

By Sir Frederick J. Braxwell, F.R.S.

The Section will have observed that, in the report of the committee,† which has just been read, no opinion is

\* A paper read before Section G. (Mechanical Sciences) of the British Association, at the York Meeting, September, 1881.

† Report of a Committee of the British Association on Patent.

which patents are now granted—last of 1862. It has, from time to time, had meetings and discussions upon the subject; and seven years ago, moved thereto by the observations by certain journals believed to be prompted by persons of position, the Society thought it desirable to have the matter thoroughly well gone into. I had the honour of reading a paper on the subject in the month of November of 1874, which resulted in a protracted discussion, and, I am glad to say, in an almost unanimous expression of opinion—an opinion fortified by that of nearly every journal that noticed the discussion, and the journals that did so were very numerous—that a Patent-law was an undoubted necessity.

The various Bills introduced by the late Lord Chancellor and the late Attorney-General, and the promise made by the President of the Board of Trade of a Bill next year, are proofs of the concurrence of the Government, both past and present, in this view. In the remarks I am about to make on the Society of Arts' Bill, I therefore intend to take it as generally conceded that there must be a Patent-law, and that the question before us is confined to the consideration of what should be the nature of that Patent-law; and I doubt not that our Chairman, in inviting the meeting to discuss this paper, will ask members to be good enough to do so in the spirit in which it is written—namely, to consider whether the Bill of the Society of Arts is one which should meet with approval or otherwise, and not to discuss the question as to whether there should, or should not be, a Patent-law at all.

At the beginning of its last Session, the Society of Arts appointed a committee, consisting of the chairman of the Society's Council (myself), Professor Abel, Mr. Alfred Carpmael, Sir Henry Cole, Captain Douglas Galton, Mr. W. H. Perkin, Dr. Siemens, and Mr. H. Trueman Wood. The committee commenced their work by drawing up a series of questions as to the mode in which a Patent-law should be framed, in regard to certain points specially enumerated; and, having done so, they asked their Secretary, Mr. H. Trueman Wood, who is helping here to-day as one of the Secretaries of Section G, to obtain and tabulate, for the information of the committee, a statement of the manner in which those various points were dealt with by the Patent-laws of other nations. Furnished with this information, the committee con-

cluded their deliberations last, before Parliament, it would be desirable to have it thoroughly canvassed. They therefore intended to summon a meeting of it the vacation, for the purpose of co-discussing it. Guided by the opinion of the Council, the Council will either retain the present form, or will make such alterations as may be deemed expedient, and will then bring the Bill which the Council of the Society of Arts desire to see passed in its entire form to the Council, in bringing the Mechanical Section of the B order that they may be benefited by will ensue here, and the opinion of the Council.

I do not think it is too much to say of Parliament have been framed on one side there was the public, and patentees; that only so much ought patentees as would lead him to come to an instance, his invention to the public attempt should be made in substance to oust him from his privileges, in or might be thrown open on the early the paper I read before the Society have already alluded, I went fully subject, and adduced arguments to interest of the community, as the development of an invention, to the public, but individual property. much time to repeat the whole but among them were the folk who had capital embarked in it to see that plant made useless by facture being changed by new unless they were tempted by the for a certain number of years, it upon a novel course which would elating the capital invested in the most patented matters, although required practical development, can only be secured by the invention an experimental stage. Under patent, the manufacturer is with necessary expense for this, an

made in a communication to the *Journal*, in answer to inquiry why liquid fuel was not employed for steam-engine purposes, and especially for steam vessels. He said, that so many attempts in this direction had been made and published, that no valid patent could be obtained, and that thus, it being nobody's interest to make the invention, the invention was not pushed, and was not brought into use. I am quite sure that Mr. Barff was perfectly right in his view of the matter. I would repeat on this subject that which I have just quoted, because it is so very true and so very apt, an expression made use of by our Chairman of to-day Dr. Siemens—namely, that for the interest of the community, if an invention were found lying, like some orphan child, in the gutter, some one should be selected, its foster father, to take up that invention.

This need of a patentee in the development of an invention was the first point the committee kept before them. The second point the committee had in view, was that, so far as possible, the connection between inventors and patents should be severed. There can, I think, be little doubt that whether in regard to the original granting of patents, or in regard to their amendment, or in regard to the trial of patent actions, lawyers are the persons least adapted to perform these functions properly. No one entertains a more respectful respect than I do for the Bench and the Bar of England, and I wish, in the interests of the public, to see them discharged of functions which they certainly they ought never to have had thrust upon them.

Unfortunately, having regard to the magnitude of the transactions involved in patent matters, there is but very little patent litigation. In the year 1874, it was ascertained for me that there were, upon an average, only 15 patent actions which went so far as to be heard by the Court of First Instance in each year; and I have no reason to suppose that that number has materially increased, if, indeed, it has increased at all. But, with respect to the few actions that are tried, a very considerable part of the expense arises from the elaborate models which are needed to instruct counsel upon the subject, and themselves have to inform the Court, and also the jury where there is one. And further, commonly, notwithstanding all the expense that is gone to, and the pains that are taken, the litigants have the chagrin of seeing that they have not been successful in making their case understood either by the Court or the jury. It may be, not even by their own counsel.

Having thus stated to you the history of the Society of Arts' Bill, and the main principles upon which it is framed, I will now briefly touch upon one or two of the leading features, showing how it has been framed with the view of carrying these principles into effect, referring the Section to the printed memorandum which has been distributed amongst them for further information on the subject. The Patent Bill has already appeared in *extenso* in the Society of Arts' *Journal* of August 5, 1881, and a few copies of it in the Parliamentary form are here, for the use of those who wish to ascertain the exact wording of any particular section.

It will be seen by the memorandum, the first proposition is, that there should be appointed, in lieu of the present Commissioners, who are all legal officials, a body of three Commissioners, one of whom should be well acquainted with Engineering, one with Chemistry, and one with Law. Power is given to the Commissioners, after the approval of the Treasury, to appoint the judicial staff. It is intended that these Commissioners should be the persons to grant patents, after a slight examination by examiners, not as to novelty, not as to utility, not as to sufficiency of invention, but simply to see that the necessary forms are complied with, and that a sufficient description is given.

The Commissioners, also, are those who would hear objections, which it is proposed to confine to persons who allege that the invention has been fraudulently

obtained from them. They are also those who would consider as to Amendments, and as to Prolongations—and it is intended that both Amendments and Prolongations should be made more easy than they are at present. And, finally, it is the Commissioners who would hear patent causes. This remitting to the Commissioners the trial of patent causes is, probably, the most thorough change made by the Bill, but the committee consider they are not without a precedent in the matter. It is now many years ago since the Railway Commissioners were appointed for the express purpose of determining questions between railway and canal companies and the public, and it is quite certain, that if it were found expedient to appoint a special body for the purpose of determining questions which involve no details of machinery, which demand no knowledge of chemistry, but which are simply questions of contract, or of the application of rates and charges of various amounts to various circumstances, still more is it needed that there should be a special tribunal for the trial of patent causes, involving, as they commonly do, matters with which no existing tribunal is competent to deal.

Amongst the other provisions it will be found, on examining the Bill, that the procedure has been modified, with the object of helping the patentee to obtain his patent more easily than at present, and more cheaply, and also with the object of rendering the patent more secure when he has once obtained it. That an attempt has been made to settle the vexed question of subject matter, by substituting a fresh definition in place of the practically obsolete one contained in the Statute of Monopolies—"A New Manufacture within this Realm."

With respect to pleas in patent actions at the present time, the defendant, even if he has undoubtedly pirated and used, without the patentee's consent, a valuable invention given to the public by the patentee, is enabled successfully to resist an action brought against him, if he can prove that some of the matter comprised within that patent, matter which he has not infringed, is not new, although the particular matter which he has infringed is new. He is also enabled to succeed in his defence, if he can show that these other matters which he has not infringed are, inadequately specified. He is also enabled to succeed in his defence, if he can show from a consideration of the Provisional Specification, that the matters claimed in the final specification were not those for which, strictly and legally speaking, the patent was granted. It is true that, if the defendant succeeds on any of these points, the patentee can commonly cure the defect in his specification by a disclaimer; yet even that is not secured to the patentee as matter of right, but as a matter of grace and favour, and is, if granted, too commonly coupled with conditions. And with regard to this question of want of novelty, it is sufficient for the defendant's purposes if a single publication—say in the British Museum—of 50 or 100 years old, not looked at once in ten years probably, and utterly unknown to those engaged in the manufacture to which the patent relates, can be raked up, and can be shown to contain, it may be, not the invention as described in the specification, but something which may be said to come within the general terms of the claim. The committee who framed the Society of Arts' Bill, as you will have gathered from what has already been said, are of opinion that it is contrary to the interests of the public that a patentee should be deprived of his invention by what, after all, are technicalities. Further, it is a very common thing for a patentee to obtain Provisional Protection, and having done so, either through being too much occupied with other matters, or through being incompetent to develop his own idea, to abandon the further proceeding with the patent, and to allow his Provisional Protection to lapse, and thereupon the Provisional Specification is made public. I believe I am right in saying that something like 20 to 25 per

for the details. I did not deem it worth my while to proceed under these circumstances, and it is certainly not worth the while of any manufacture of chain cables to carry out the idea which was in my mind, and in that Provisional Specification. It is on such grounds as these, that the committee who have prepared the Patent Bill of the Society of Arts, propose the Provisional Specification should be a merely temporary document, and that it should never be made public so that whether a patent be granted, or whether the Provisional Protection be suffered to lapse, the document should be destroyed. Similarly, it appeared to the committee that it was inexpedient a patent should be rendered invalid by any dormant publication, such as a book in the British Museum, and therefore they proposed, that unless an invention can be proved to have been in use within thirty years, no mere publication, unaccompanied by use, should be considered an anticipation of a patent. With respect to the term of a patent, it will be seen that the committee suggest the American term of 17 years, coupled with the power of Prolongation for a further 11 years. The term of 17 years has been taken, coupled with this power, in preference to the term of 21 years proposed in the Government Bill of 1879, unaccompanied by Prolongation, as the committee deemed that 17 years, if the patent were successful, would afford the patentee sufficient remuneration, and also, that having once established a body competent to deal with patent matters, there would no longer remain the difficulty of obtaining satisfactory decisions in cases of Prolongation. The scale of fees proposed, in order to obtain a patent, is that of the Government Bill of 1879, and, as regards the subsequent payments, is practically the same as was proposed in that Bill.

In this, the most recent Government Bill, provisions were made for the cessation of the patent if the invention were not put to work within a given time, and, in addition, provisions were made that compulsory licenses should be granted by the patentee. The committee of the British Association which considered the Government Bill of 1879, strongly urged the undesirability of the first of these provisions, and pointed out that where a patentee was bound to grant a license, there was no reason why he should be deprived of his patent, if he himself failed to put it to work, and they gave instances in which it would be extremely difficult for the patentee to obtain

Jeremiah Head, Dr. Siemens, Mr. H. Trueman Wood, and others too.

Sir Antonio Brady said—I should the Inventors' Institute, to express at the lucid and admirable discourse to. Till now the Patent-law has been go to law, and it has destroyed almost that would have been granted if w law. The society which I represent cheap patents, and the only part don't think will meet the views of the tute is that the fees are not reduced what we think would be advisable. a very unrighteous thing to tax any exclusively—that taxes ought to be further, that it is not right to tax particularly to tax that brain power rest the advance and the prosperity of this great nation. We have advanced progress towards cheap patents and we think that the Patent-law be more our model than it is no the country should not make patents, other than what is ne the Patent-office, and to provide patentees by having a proper register endorse the views of Sir Frederick propriety of having a first examination character as proposed in this I the Patent-office ought to be able to ance to inventors that is possible, fo heretofore has been for a patentee, to ascertain what has registers have been so imperfect, a making examination is such, that office ought to be organized in such able to give advice and assistance to vent them from running their heads commonly happens now that the patent, whether the rightful owner is not. It is impossible to suppress present system, if two people were the same day, they would not this Bill it would be impossible we think it is a marvellous improvement system. Moreover, there are v

y of the man who owns it. The law cannot give absolute power over it, because the Courts must many questions of patent rights afterwards; but it is a marvellous improvement that this Bill ve inventors generally, because it will be a very thing for any person to contest a patent which as granted under the provisions of this Bill; as now I am not wrong in saying that Sir Henry ar, who has enriched the whole world by his in- as, has been put to enormous expense to defend f against certain patents which were lying nt, and has been obliged to compensate the of them rather than go to law in such cases. I there are several other instances in which a small has cost £50,000 or £80,000 to defend it, which t be the case under such a Bill as this. Further, in esent day, the inventive genius of our people should ured in every possible way. This is a small ry. We cannot compete with larger countries, we utilise the brains of our people, and give them stance of the Patent-laws, which will encourage inventive genius. You spoke, sir, just now, about lemons, whom I am very glad to see in the room. ve that I am right in saying that he could not get tent in Germany, and we have had the advantage splendid genius and of his inventions, which we I not have possessed but for the Patent-law. I e there are other instances—not, perhaps, of such lent as this—and therefore I say that it is of the st possible moment to this commercial country to age the inventive genius of our people to the st possible extent; and I don't think there can be jection in the mind of any sane man to extend nt over a period of 17 years, as this Bill proposes. ld have preferred 20 years, as in recent Bills, he Bill provides a power of extending the term certain circumstances.

. Jeremiah Head —As one of the numerous class of bees, I have asked for a moment or two to pay my sum of thanks to Sir Frederick Bramwell for g brought this question before us. I can so all he says of the way that the law, as it now s, seems to punish the patentee as much as ever it . A man who has an invention has no way of ring the information necessary, except by appeal- to a patent agent, and although there is no a to doubt that patent agents, as a rule, are honest, is clear that their interest is rather in favour of aging a man to go on. The patentee goes on pends, before he can complete his patent, some- like £40, and in three years time he has to spend r £50. That is a very large sum of money, et it does not at all include what he has pend in experiments. It is proved, by the number of patents that are dropped at the y stages, that it would be better if a ty of them had never been taken out. They een found either not to be new, or the inventors not ready to incur lightly the great expense of ng them to perfection, finding after two or three hat they had better drop them, after having lost e money, of time, and of thought, and that, in ey were not the men to bring out the thing at o doubt, according to our present law, the Patent- as got the man's fees, and does not seem to care, at man is a disappointed man, and, therefore, I hat it is a disadvantage that he should have s his time and his money over an invention . had better have been brought out, if at all, me one else. I did not quite gather from ederick Bramwell whether he proposed in this at there should be any way or any body to whom entor, getting an idea, could write, on paying a fee, and have his ideas submitted to some sort of inary test; whether on payment of such a fee he be referred to this, that, or the other patent pre-

viously taken out, or some suggestion made to him, which, would, in many cases, discourage him from going on. I think that is very much wanted indeed, and it is only to be obtained now by appealing to patent agents, who do not always advise disinterestedly.

Mr. Barff—I just wish to ask one question, if there is any special reason for making the payment at the end of the fourth year so great as £10. We know that there are a great many patents that in four years cannot have paid themselves, and this tax of £10 seems rather high. The great advantage of an improved Patent-law would be that it would give men a greater interest in their work, as they would have some encouragement to study what they were doing every day, with a view to its improvement, and get a patent for the improvement. But I merely wish to ask whether this payment of £10 at the end of the fourth year is not higher than it need be.

Sir Frederick Bramwell—The payment at the end of the fourth year instead of £10 is £30.

Dr. Siemens, F.R.S.—If anything were needed to show the difficulty surrounding the framing of a good and just Patent-law, the observations that have fallen from the last two speakers would furnish incidental proof. Mr. Head, who is so well known for his mechanical talent, suggests that the obtaining of a patent should be made very difficult—that the patentee should not only prove that he had novelty, but that he had usefulness. I am afraid that, if that suggestion were adopted, many valuable patents would fall to the ground or be stillborn. It is the very essence of an invention that it cannot be worked in its first conception, because an invention is not a mere idea. An idea may strike the mind at one instant, but an invention is necessarily the result of labour—mental and physical—and of expenditure, and there is hardly an invention ever brought out that in its first stage would have stood such a test. I cannot agree with Mr. Head in supposing that all those inventions that have not taken immediate effect, and enriched the patentees, are so much loss to the country. On the contrary, although the inventor is to be felt for who has not reaped any benefit from his invention and for his labour, yet the public at large profits by it, because it may form the stepping-stone for somebody else to carry the idea to its practical point. The Patent-law must not be based upon the idea that all difficulties will be done away with, that all men are to be made happy, and that there is to be no legal contention of any sort. That would be a chimera such as could not reasonably be expected. If it is difficult to establish a title to landed property, surely it may be reasonably supposed that it is as difficult to establish a title to the product of the mind; and all we can do is to render the administration of that property as simple and as just all round as it possibly can be made, humanly speaking. The Patent-law worked out nominally by the Society of Arts, but in reality by my excellent friend, Sir Frederick Bramwell, is, I think, the best considered, and, perhaps, the most perfect attempt at a just and equitable law on the subject; and I, as one of the committee, can only hope that it will find favour in this Section in order that it may be strengthened by the weight of the British Association, and that the Legislature of the country may take a similar view. It is idle to discuss partial questions connected with such a law, as, for instance, that the fees to be paid by a patentee should be a great deal less. It is now proposed also to extend the operation of the patent over 21 years instead of 17. You may depend upon this that all these questions have been very carefully considered by the committee, and also tested by legal opinion, and that this Bill is the result of the careful and long meditations on the subject by Sir Frederick Bramwell, and of the discussions that took place in the committee, at

Mr. H. Trueman Wood—I should like to be allowed to answer an objection, which has not been brought forward here, but which has appeared in one or two very influential journals, about the Society of Arts' Patent Bill. It has been said that the provision in it for examination would give the Commissioners the power of stopping invention, by refusing to allow an applicant to take out a patent. Now, as a matter of fact, the power given by this Bill is considerably less than that which is at present possessed by the law officers of the Crown; and I do not think it has been asserted that the present Patent-law, whatever else may be its defects, gives the power to stop invention. The very slight examination permitted under this Bill, is not an examination into merit or into novelty; it is merely a sufficient examination to enable the office to say that the matter in respect of which the application is made is really connected with Science, or Manufactures, or Commerce, and ought to be protected by a patent. My only reason for making this remark now is, that this objection has been urged very strongly, and I should be glad to have it put on record that no such power exists in the Bill. Indeed any person who reads it carefully will not be able to find any such power in it.

speaker was quite right in suppos-  
was not that the Bill should be  
accepted *en bloc*, but that we should  
the opinions of the members present  
am very glad that we have had that  
examination as to novelty. It is or  
cult things to determine as to what  
should be made or should not be  
difficult because of the danger of  
as to what should be considered as  
invention. I think I am right.  
Germany, Dr. Siemens was refused  
regenerative furnace, on the ground  
a cavity had been heated by a fire  
the fire being removed, the heat ha  
cook whatever food was put within  
process the examiner held to anticip  
furnace. I am aware this is an ext  
it may be said we might reasonably  
intelligent examinations with regar

deliberation the Society of Arts Co  
conclusion that it was best to omi  
But I am sure this is just one of those  
the Council of the Society of Arts  
to have had an expression of opini  
present. With respect to the sugges  
visional specification, the clause in  
sub-section 3—sets forth that "On  
of a patent, or of failure to prefer  
time allowed, the provisional speci  
destroyed in the Patent-office, and un  
its contents shall be kept secret."  
to prevent fraud, and to prevent t  
final or complete specification and  
that which the patentee never in  
he had derived from somebody else  
provisional protection—to prevent  
the provisional specification is w  
when you have an examiner, as  
Bill, whose duty it would be to asce  
pleted specification does not contain  
a fair development of that contain

monal specification should be destroyed as being, in the public, a bar to further improvement. But the question whether, in those cases where the patent is not, the provisional specification should be destroyed, which will be well considered by the Society at the Council finally adopt the Bill. With respect to question of fees, if they are made too low, I am sure there might be such a mass of patents granted that they would be a nuisance; and I cannot help thinking that the opponents of a Patent-law altogether are chuckle at the notion of, say, a shilling fee or less of that kind. I am aware, on the other hand, that it may be said it is a very hard thing that, to a man of great ability and ingenuity does not cost £10, and a man of less ability and ingenuity, the former should be debarred from the protection which the latter can get. I am one of those who desire earnestly that all those who have any good in them should be able to bring it out, and reap advantage for themselves, while giving the benefit of it to the public, but there are a variety of things we should consider, all people to have if it were possible, but, really, it is one of the pains of poverty that they do not have them, and, therefore, those who frame a law of this kind have to hold the balance between the desire of affording cheap patents and their fear

If patents be made too cheap, they will be easily taken out, and will become so obnoxious as to lead to the abolition of patents altogether. Let me ask the question of the necessity, in the interest of the advancement of patents, of something more than nominal fees, by asking whether any one present would think that patents could survive if they were granted gratuitously. I am sure you feel that, if you issued gratuitous patents, they would be intolerable. What we should be it is most difficult to determine. Far from saying that the Society of Arts have adopted a light scale. I feel that I shall not be very wrong if I state that the committee were glad to base them on a scale in the Bill of 1879, which scale seemed to have with very general approval, and they adopted it, such modifications as were needed to vary the amount of subsequent payments in a Bill that provides for the duration of a patent in lieu of the 21 years provided in the 1879 Bill. With respect to Mr. P's suggestion, it seems, as far as I could follow him, he thought there should be a sort of friendly Board which an intending patentee could go and say in substance, "I have invented this; do you think it is worth patenting?" Now it does appear to me, with respect, that that is a thing that could not possibly be done. I feel certain that that kind of paternal legislation would not do. Imagine a Board to which an intending litigant, in a civil action, could go and say, "I am thinking of bringing an action against you in respect to that right of way over my field. Do you think I am likely to succeed?" I am glad to see that, except on the subject of the scale of fees, on which I have already fully remarked, the Bill has the approval of Sir Antonio Brady. I believe I have, although in a very cursory manner, answered the suggestions that have been made. With respect to the provision of our Bill for removing patents from the hands of the lawyer, I am glad to say that it meets, generally, with the approval of those now in power. So because the announcement made to us is, not the Government Bill of 1882 is to emanate from Lord Chancellor or from the Attorney-General, but it is to proceed from the Board of Trade. We have written to the principal persons interested in the matter, and have sent copies of the Bill to them, and at the same time we hope that between now and the meeting of Parliament the Bill may receive general approval that the Government may see no way to incorporate its provisions in the measures now proposed to bring forward. With these observations, I conclude what I have to say, except this, that

I have to thank you most warmly for the close attention you have paid to a subject which, although it is done, no doubt, of great importance, is, on the other hand, an extremely dry one. The question of the Patent-law is one I have studied for many years, and I, no doubt, have worked hard in the preparation of the Society of Arts' Patent Bill; but Dr. Siemens was pleased to give me far more credit than is my due, and omitted to tell you the share he and others have had in the work. He did not tell you that he was the chairman of the successive committees of the British Association that have sat on this very matter. It was the fact of finding myself in the position of chairman of the Society of Arts that led me to suggest that the course they have followed should be pursued by that Society, while we had the advantage of the assistance of many gentlemen who are members of the committee of the British Association. I trust the Committee of Recommendations will agree to the demand made, that the Patents Committee should be continued, and you may reply upon it that when the Government Bill is brought forward it will be thoroughly scrutinised, and we will do our best to make such alterations in it as will bring it towards the measure prepared with so much labour by the Society of Arts.

Mr. T. Hawkesley.—You have all listened with much attention to the eloquent address of my friend Sir Frederick Bramwell. The subject is one in which I take a great interest, but it is far too complex for me to express my opinion upon it at the present period of the day. But I am sure you will all agree that Sir Frederick Bramwell is entitled to an enthusiastic vote of thanks. I therefore beg to propose your thanks to him from the chair.

Sir Frederick Bramwell.—I am very much obliged to you for your vote of thanks. Let me say, in conclusion, that if we obtain a really good Patent Act I shall be more than rewarded for the continued pains I have bestowed on the question—the best reward I can get is to see a good Bill embodying the bulk of these clauses.

#### FREDERIC SAUVAGE.

The *Times* gives a sketch of the life of Frederic Sauvage, to whom the people of Boulogne having just erected a statue, as the inventor of the screw propeller. His claim to this honour rests on the fact that in 1832, hearing that the French Government proposed to build a number of paddle steamers, he was led to devise a better means of propulsion, and eventually he constructed a screw. Early in that year Sauvage exhibited to the Boulogne authorities his new invention, which was highly approved. As he was anxious to bring it under the notice of Government, he gave up his Boulogne residence and left for Paris, where he took out a patent for 15 years. The screw was acknowledged to have its advantages with small boats, but the Commissioners who sat by order of the Minister of Marine to report on it concluded that it would be of no use for large vessels. The English Government in 1835, it is stated by the *Times*, offered him a sum for the invention, on the condition that it was to become the exclusive property of England, but the inventor, who was at that time stricken down by poverty, would not consent. It is further said that Sir Francis Pettit Smith derived his first idea of a screw from a visit to Sauvage's workshop. In 1841, Sauvage made an agreement with a ship-builder and an engineer for the construction of a steam-boat, to which the screw was to be fitted, he giving the plans, while they carried them out, and at their own expense, but the agreement, owing to a technical misunderstanding, was badly worded. The boat was built and fitted, but not as Sauvage wished, and the two others took all the credit. The unlucky inventor, forsaken by all, after many years of toil, was in the year

little attention outside his own country. In England, it will be remembered, in 1770, James Watt, writing to Dr. Small, proposed to use one of his steam-engines to drive a screw for the propulsion of a ship. In 1770, the American, Bushnell, described a submarine boat, propelled by a screw. Trevithick patented a screw propeller in 1816; and before him, in 1800, Edward Shorter patented a propeller, which was afterwards, in 1802, tried on H.M.'s ships *Dragon* and *Superb*. In America, Stevens, in 1804, tried to propel a boat by a screw. In 1816, Millington described a screw with a very ingenious steering arrangement connected to it, and this was apparently the first of a great number of attempts which have been made in that direction; all, as yet, unsuccessful. From this date till the date of F. Pettit Smith's invention (1836), the records of the Patent-office show that many minds were working in the same direction. The point of Smith's invention was the placing of the screw propeller in the dead wood of the vessel, nor has it ever been claimed for Smith that he was the inventor of the screw propeller, though he was, there seems little doubt, the one to bring it into actual use. There seems little question that Sauvage did nothing more than was done by very many others—by Watt, Trevithick, and the rest—conceived a most valuable idea, but never carried it beyond the stage of a model.

#### THE MINERAL RESOURCES OF TURKEY.

Consul Wrench in a recent report states, with reference to the resources of Turkey, that although the country seems with mineral wealth of various kinds, they are left almost undeveloped, except in the case of some products which are elsewhere rare, but found abundantly and of great richness and purity in the Levant. The meerschaum from Eskişehir, in the district of Kutayah, still continues to hold its supremacy; in recent times both emery stone and chromate of iron have been exported from Turkey in increasing quantities, and now the markets of the world are mainly dependent on this country for supplies of these minerals. Manganese ores, crystalline pyrolusite of remarkable richness and purity, have also been to some extent exported of late years to Europe. Boracite

and during that period they are at £1,500,000 profit. From the large size of the deposits, the supply of the considered practically inexhaustible persons assume that the quantities be computed by millions of tons. The whole of these deposits of boracite Englishmen by right of discovery to Consul Wrench states that though it dictation to make, yet there is ground Turkey in time will also become mines, as he has been informed by them from the outset connected with the in Turkey, and who have acquired knowledge on the subject, that "the series of auriferous deposits." In have been found, some of them associated worth from £2,000 to £6,500 per ton. concession for an argentiferous gold has been granted; this mine is at Jiller, about 12 miles from the mine consists of a quartz reef 40 projecting several feet above the surface for nearly half a mile in length, and the summit of a mountain of mica-schist feet high, down its side to the valley several ancient galleries in this reef are the ruins called "Kalé-Tath," an historic fortress constructed of rough From the top of the reef near the Wrench, when on a visit to the mine struck off some pieces of quartz, which part of the precious metal was visible—on being assayed, proved to be of the value of 8 os. 3 dwt. 10 gr. of gold per ton sample proved even richer, for the yield of gold per ton of ore; other samples 13 dwt. down to 19 dwt. 10 gr. of gold together with a nearly equal quantity of reef appeared auriferous throughout value appears to be attached to this; the size and richness of the reef, facilities for working, as it can be open quarry with a natural drainage plane for covering the ore to the base water power is available for crushing

## COLOUR BLINDNESS.

E. Brudenell Carter, F.R.C.S.

—DELIVERED MONDAY, MAY 16, 1881.

1. *Nature of colour vision generally. Light—its composition. The prismatic invisibility of certain elements of the spectrum to the colour-blind. Appearance of the spectrum to the colour-blind. Varieties of colour blindness.*

It has been known to those engaged in the natural philosophy, and, to some extent, general public, that certain persons are deficient as not to possess the same complete sensation as the great bulk of the human race. Until lately, however, defective vision was considered to be a somewhat rare matter for philosophical curiosity, and of only slight practical importance. It is reserved for our own time to discover that colour blindness affects rather more than four per cent. of the whole male population of civilised countries, and that it affects certain classes in a disproportionate proportion; while, at the same time, it has sprung up, and have attained to a rapid development, in which the employment of colour-blind persons may easily occasion, and it has occasioned, great calamities. The progress of railway traffic and of steam navigation is almost entirely dependent upon the use of signals; and for these signals the colour-blind are employed as red and green, the colour-blind fall into error and confusion. There is a general feeling among practical men that these two colours cannot be replaced for signalling purposes; and hence it has become imperative to exclude the colour-blind from the service in which the lives of large numbers of people may be offered up as sacrifices to their vanity. There are, in Great Britain, about 100,000 employed as engine drivers; and there are among these, about 400 who are colour-blind, whose work is a source of never ending danger to themselves and others.

With this intention, in this preliminary lecture, of the nature of colour blindness; and for this purpose, it will be necessary to pave

the way by speaking of the nature of colour vision. The many among my audience who are fully acquainted with the existing state of knowledge on this subject must be asked to pardon the introduction of elementary matter, which seems necessary in order to give any approach to completeness to my discourse.

The quality to which we give the name of colour depends entirely upon the kind of light which is transmitted through a coloured medium, or reflected from the surface of a coloured opaque substance. In order to make this clear, we must remember that we see surrounding objects only by virtue of the light proceeding from them, and that this light is derived, either directly or indirectly, from the sun. If we carry the matter a step farther, we find that what we describe as light is merely an impression made upon our eyes by vibration or wave movement; and that this wave movement occurs in an infinitely subtle fluid medium, called luminiferous ether, which pervades space, and fills the intervals between the molecules of all transparent substances. Just as water is a more mobile and subtle fluid than mercury, or air than water, or hydrogen gas than air, so this hypothetical ether is more subtle than hydrogen; and it is indeed so subtle that it transcends our knowledge entirely, except by its effects in the propagation of the waves of light. A study of the phenomena of light shows these phenomena to be of a kind which only wave movement can explain, and which bear a striking analogy to those produced by the visible waves of water, or by the invisible waves of air which we recognise under the name of sound. I must therefore ask you to picture to yourselves the whole universe as filled and pervaded with this infinitely subtle and mobile luminiferous or light-carrying ether; and to realise that what we describe as light is nothing more than a vibration or wave movement in this ether, just as sound is nothing more than a comparatively coarse vibration or wave movement in air. Between the wave movements of sound and those of light there are differences as well as resemblances, but the former do not at present fall within the scope of our notice.

In the propagation of wave movement, it must be remembered, the particles which form the wave do not themselves travel, but only oscillate. If we stand by the smooth surface of a pool of water, on which some corks are floating, and if we throw a stone into the middle of the pool, we shall initiate a violent wave movement, which will be quickly propagated in all directions from the centre of disturbance to the extreme margin of the water. The surface of this water will be thrown into alternate elevations and depressions, and these elevations and depressions will travel to the shore; but the water in which they occur does not travel, but only moves up and down. If we watch the floating corks, we shall see the whole mechanism of the process. The corks will bob up and down on the successive waves, but will retain their original places on the pool; and, when the wave movement subsides, the corks will be left where they were at first. If the propagation of the waves is checked by some obstacle, as by a wall bounding the pool, they will be turned back, and the secondary or reflected waves thus formed will intermingle with those which are still advancing from the centre.

and position of its surface. The human eye contains a mechanism by means of which the light waves which enter it are re-arranged upon the nerve tissue subservient to vision, in a reduced reproduction of the pattern in which they left the obstacle, and so we are said to see the objects around us. What is meant by seeing, is that the vibratory movement of the luminiferous ether, being first rearranged within the eye according to the way in which it was reflected from the visible object, produces corresponding molecular movement in the nerve tissue, and this movement becomes the subject of consciousness. All vision depends upon the nerve tissue being made to vibrate in unison with the vibrations which constitute light.

The light which we receive from the sun is white or colourless; and hence, if this light were pure and unmixed, so that it was reflected from all surfaces precisely as it fell upon them, subject only to more or less diminution of quantity from absorption or in transmission, the effect would be that the pattern or picture formed within the eye would exhibit differences of light and shade alone. The visible world would be deprived of colour, and would be reduced to the level of a "black and white" exhibition.

In reality, however, the solar light is a mixture produced by the blending together of three different rates and magnitudes of vibration. The waves of largest size and of the slowest oscillation, when we receive them alone, produce a nerve movement which excites the sensation that we call red. The waves of intermediate size and quickness, when we receive them alone, produce a nerve movement which excites the sensation that we call green, and the smallest and most rapid waves produce a nerve movement which excites the sensation that we call violet. For the foundation of this discovery the world was indebted to the genius of Newton.

Material substances may be roughly divided, in

glass fairly and fully, at right angles but obliquely, so that one end of each surface before the other. The result is that one end is more retarded and that the course of the wave is altered. This is called refraction, and you will observe that whereas the plate of glass held vertically leaves the position of the bright line unchanged, the plate held obliquely bends the beam of light, and alters the position.

Now, although all light is thus bent when it falls obliquely upon the surface of a transparent medium, the degree of bending depends very much upon the magnitude of the wave movement; being much more for small and rapid waves than for large and slow ones. Hence, by means of a prism, it is possible to produce a high degree of refraction, able to split up the solar light into its constituent parts, and to exhibit them separately. If you now rekindle the lamp, and will place a prism in the track of the beam, you will observe what is called the prismatic spectrum, the immortal discovery of Newton.

The first thing you will observe is that, although as a whole is bent out of its course, it produces upon your eyes the impression of three distinct colours. These are those which are bent the most, and produce the impression of green; those which are bent a moderate degree, and those which produce the impression of red are bent least of all. This is the difference of the amount of bending, which is incidental to the difference of wave movement, which explains the principle upon which the solar light is split up into its constituent colours.

The next thing to be observed is that the spectrum is not limited to the three named, red, green, and violet, but includes others also. We may now abandon light, and turn to a pictorial representation of the spectrum.

first arrived at upon the point. It was reserved for the late Professor Clerk Maxwell to clear up all doubt upon this subject, and to prove beyond question that the true primaries are red, green, and violet, or, as he called it, blue. Orange is a mixture of red and green with the red in excess; yellow a similar mixture with the green in excess; while blue and indigo are mixtures of green with violet. The difficulties which stood in the way of an accurate determination of the primaries were largely due to an element of confusion introduced by the use of pigments for the purposes of experiment. People who were accustomed to mix blue paint and yellow paint to produce green, found it difficult to believe that the green of the spectrum was anything more than a mixture of the blue and yellow by which it was bordered; but as Mr. Ladd will show you, an admixture of the blue and yellow of the spectrum does not produce green, but white. The blue light being a compound of green with violet, and the yellow light being a compound of green with red, the two together afford the three primaries, which combine to form white. In the paints, on the contrary, the material which appears blue absorbs and quenches red—while the material which appears yellow absorbs and quenches violet; so that only the green, which is common to both, is reflected unchanged to the spectator from the mixture.

We have now arrived at the point that sunlight consists of three colours, or, more properly, of three in three different states of vibration; and my next proposition is that nearly all substances have differences of behaviour in relation to these three states respectively. Speaking of light generally, we may say that it is affected by matter in three chief ways. It is either reflected from surfaces, or transmitted through substances, or absorbed and quenched within their mass, and it undergoes all these operations in some degree in every case. To say that a surface is perfectly white in sunlight is a way of stating that it not only reflects back to the spectator a large amount of the light which it receives, but that it also reflects it in unchanged proportion of its constituent parts, turning back long, short, and medium waves with absolute impartiality. To say that a surface is black in sunlight is a way of stating not only that it absorbs nearly all the light it receives, and quenches this light by arresting the wave movement within its mass, but that it also absorbs and quenches impartially with no distinction between wave lengths. To say that a surface is red, is to say that it absorbs and quenches the green and violet rays, but that it permits the red to be reflected, and the same applies to the other primary colours also. A green surface is one which reflects green rays while it absorbs and quenches red and violet, and a violet surface is one which reflects violet, but quenches red and green. In order to illustrate this, Mr. Ladd will once more throw the prismatic spectrum on the screen. A piece of white paper, wherever we hold it, reflects the colour which falls upon it, and appears red, yellow, green, or blue, according to its position. A piece of black paper, wherever we hold it, absorbs the light which falls upon it, and appears black without reference to its position. A piece of red ribbon, held in the

red end of the spectrum, receives only light which it is capable of reflecting, and shows its proper colour with unusual brilliancy; but, if we carry it into the green portion, it receives nothing which it does not absorb, and it appears entirely black. A piece of green ribbon, on the other hand, is vivid in the green portion, and appears black in the red.

We thus arrive at the fact, that the apparent colour of any object is due to the selective power which it possesses of quenching certain elements of white light, while it reflects the rest, and the seeming difficulty of reconciling the infinite variety of colour with the fewness of the three elementary or primary colours will disappear as soon as we consider how these three primaries are produced. Very large numbers can hardly be realised by the mind, and there would be no advantage in stating the figures which I am about to give with entire exactness, even if that were attainable. I will be content to say that the lengths of the waves of light are such that about 35,000 waves of red, about 50,000 waves of green, and about 60,000 waves of violet, would be comprised within the length of a single inch. If we take the medium, the 50,000 waves in an inch as the basis of a farther calculation, and consider that the speed of the propagation of light is about 190,000 miles in a second of time, we may find by simple multiplication that the actual number of the waves which produce the sensation of light amounts to hundreds of billions in a second. We must, therefore, regard each primary colour as being composed of an infinite number of units, and the number of possible combinations from billions of units of red, billions of units of green and billions of units of violet, if not absolutely incalculable, is at least inexhaustable. It must be remembered, moreover, that these combinations do not possess any obvious character to declare them for the mixtures which they are. The simple mixtures, such as orange, yellow, blue, and indigo, were long believed to be themselves primaries, and the effect of a mixture is not a question of the mere addition or subtraction of a tint, but is rather a modification of the whole character of the aggregate resulting wave movement by the various clashing, blendings, and interferences of one series of waves with the rest. The spectator who looks down from a favourable position upon the "multitudinous laughter" of the ocean, and who sees upon its surface a movement which is never the same, may realise from that magnified representation something of the possible diversity which the endless combinations of the waves of colour may be equally capable of producing.

Excepting in the prismatic spectrum, carefully obtained under specified conditions, we never see a primary colour in a state of purity. The colours of all natural objects are mixtures; and even those which appear identical with the pure red or the pure green may be easily shown to be mixtures by careful experiment. If we take such an object as a geranium petal, which we should call almost pure red, and look at it by sunlight, a portion of that sunlight is reflected back to us absolutely from the surface of the petal, and that portion, which has not at all penetrated into the tissue, is reflected unchanged, or as white light. The light

green, we must not be supposed to imply, otherwise than when speaking roughly and inexactly, that it transmits the red rays or the green rays and quenches all others. What it does, as a matter of fact, is to transmit a mixture, in which red or green is predominant, but from which other colours are not excluded. Mr. Ladd will throw the electric beam once more upon the screen, and will then place before the lantern a piece of red glass, such as is used for the danger signals on railways. You see the white spot is transformed into what you would call a red one; and you would be inclined to say that the light falling upon the screen was red light only, the glass having intercepted all the rest. We will test this by the interposition of a prism, which breaks up the so-called red light into its component parts, and shows us that it contains also a certain quantity of violet. We will now repeat the experiment with the green glass used for railway lanterns; and here again we shall find that the green light, as we should at first be inclined to call it, has by no means been deprived of all admixture with other colours. In other words, the colours which we call, in common parlance, red or green, are not accurately described by this form of expression. In reality, they are mixtures, in the composition of which red or green is no more than the predominant ingredient. To this element in the question I am anxious especially to direct attention, because we shall have to return to it hereafter.

If we pass on now to the effects of these colours upon the sense of sight, we shall find that the healthy human eye, as it is organised in the great majority of people, not only recognises the quantitative arrangement of the light in the pictures which are formed upon its retina or nervous screen, but also recognises differences in the rapidity and amplitude of the wave movement of which this light is composed; seeing, in other words, not only form and light and shade, but colour also. There are others, however, in whom

to him.

The nervous apparatus of the sense of vision is formed of the termination of two obviously different kinds, the rods and the cones of the retina. The rods are most abundant in the central vision, both for form and colour, and the cones are most abundant in the peripheral vision, both for form and colour, where vision is comparatively defective. It was Dr. Young, whose conjecture, in modified form, has been adopted, that the cones may be of three kinds, of which one responds to sensations of green, a second to sensations of red, and a third to sensations of violet; and that, in the persons who are called colour-blind, one of these varieties is dormant, or wanting. It seems to be certain that there are certain difficulties in the way of this hypothesis; concerning the formula, "it may be so." Another fact is to remind you that the strings of a piano, tuned to a certain pitch, thrown into vibration by waves communicated to the air by other strings tuned in a similar manner; while strings tuned differently remain unaffected, would at once respond to vibrations fitted to excite them. Mr. Ladd, of tuning forks with which to experiment, and you will observe that, when one fork is struck, it throws the other into vibration next after the pitch of one of the prongs with a lump of wax. You will observe that, in this state, the fork is affected by its fellow; while, if the first fork were to be loaded precisely to the point where its power to produce vibration would first be restored. Now, the deal of analogy between the

he facts; and these, as we shall see pre-are very curious and interesting.

I have just stated, Professor Helmholtz, in unit of the theory of colour sensation pro-l by Young, assumes that there are in mal eye three kinds of nerve fibres, mulation of fibres of the first kind pro-e sensation of red, that stimulation of the ind produces the sensation of green, and mulation of the third kind produces the n of violet. He assumes also that neous or monochromatic light excites aree kinds of fibres in varying degrees ig to the wave lengths. The red-perceptive ill be most stimulated by light of the wave-length, and the violet-perceptive by the smallest wave-length. It must also ned, however, that each colour excites all nds of fibres, although it excites one kind ore strongly than the others. Helmholtz es this by the diagram shown in Fig. 1,

Fig. 1.

sh the colours of the spectrum, omitting ligo, are arranged in a row from red to und in which the three curves represent the y of stimulation of the three kinds of The curve marked 1 represents the stimu-f the red-perceptive fibres, the curve marked ents the stimulation of the green-perceptive, curve marked 3 represents the stimulation iet-perceptive fibres.

le red strongly stimulates the red-per- less the other two: sensation, red.

le yellow stimulates moderately the red and perceptive, feebly the violet: sensation,

le blue stimulates moderately the green and erceptive fibres, feebly the red: sensation,

le violet stimulates strongly the violet-per- feebly the other fibres: sensation, violet.

lly strong stimulation of all the fibres gives ation of white or whitish colours.

essor Helmholtz is fully aware of the ies which impede the acceptance of Young's ais of there being three kinds of fibres, suggests, as a possible modification, that parate functions may be discharged by re. Whether this be so, it is not at pre-her possible or very important to ascertain; her of the foregoing hypotheses, or the ais of variations of tension rendering the ecapable of responding to certain rates ation, will serve almost equally well to the phenomena which have been observed. eaking of these phenomena, Professor en has made use of Helmholtz's diagram, modified it in such a manner as to exhibit sts of colour blindness. I could not pre-

sent the whole question to you in any other way so well as by quoting his words, which I take from the American translation published by the Smithsonian Institution. He says:—

"To explain the abnormal sense of colours by the theory of the normal, we can, in advance, suppose various possibilities. Let us conceive that one of the three fundamental perceptions is wanting, or that one of the primitive colours is absent: it is clear that the whole chromatic system will be upset. It is evident, therefore, that this system must be completely different, according to the absence of one or the other of the three primitive colours. It is virtually just in this way that it has been attempted to explain cases of a strongly marked defect in the chromatic sense, or genuine types of blindness to colour, found in real life. The term colour-blindness has been justified by this, as it indicates in each case a genuine blindness to one of the primary colours. In this way, therefore, we distinguish, according to the kind of element wanting, three classes of blindness: namely, red-blindness, green-blindness, and violet-blindness."

According to the theory, blindness to red is due to the absence or paralysis of the organs perceiving red. Red-blindness, then, has but two fundamental colours, which, adhering strictly to the theory, are green and violet. The curves in the second diagram distinctly show what aspects the various kinds of light must have for a person who is placed in such a condition.

The red of the spectrum, which feebly excites the perceptive organs of green, and scarcely at all those of violet, must appear to the red-blind as a saturated green of a feeble intensity, more saturated than green as visible to the normal eye, for into this sensible portions of the other primitive colours enter. Feebly luminous red, which affects the perceptive organs of red in a normal eye sufficiently, does not on the other hand sufficiently excite the perceptive organs of green in the red-blind, and it therefore seems to them black. The yellow of the spectrum seems to them a green, saturated and intensely luminous, and, as it constitutes the precisely saturated and very intense shade of that colour, it can be understood how the red-blind select the name of that colour, and call all those tints that are, properly speaking, green, yellow. Green shows, as compared with the preceding colours, a more sensible addition of the other primaries, and it consequently appears like a more intense but whitish shade of the same colours as yellow and red. The greatest intensity of light in the spectrum, according to Seebeck, does not appear to the red-blind to be in the yellow region, as it does to the normal eye, but rather in that of the blue green. In reality, if the excitation of the perceptive organs of green, as it is necessary to assume, is strongest for green, the maximum of the total excitation of the red-blind must be found slightly toward the blue side, because the excitation of the organs perceiving violet is then increased. The white of the red-blind is naturally a combination of their two primitive colours in a determinate proportion, a combination which appears blue-grey to the normal sight; and this is why the red-blind regards as grey the transition colours of the spectrum from green to blue. Then the other colour of the spectrum, which the red-blind call blue, preponderates, because indigo-blue, though somewhat whitish according to their chromatic sense, is to them.

to be of the same colour; and if, in especial cases, he knows how to discriminate between them, his judgment is simply guided by the intensity of the light. The intensity of the light is much more feeble, as shown by diagram 2, in red than in green. If then, a red-blind individual finds that a red and a green tint are exactly alike, the green would, to a normal eye, be much less intense than the red. This is distinctly shown by the vertical dotted lines between R and O, and between Y and G, in Diagram 2, and is also entirely confirmed by experience.

Fig. 2.

Green-blindness derives its origin, according to the theory, from the absence or paralysis of the perceptive elements of green. The green-blind has therefore only two fundamental colours, red and violet, and the spectrum for green blindness should be constructed as in diagram 3. In such a

Fig. 3.

case the red of the spectrum, which strongly excites the perceptive organs of red, and but very faintly those of violet, must appear to the green-blind as an extremely saturated red, but of a light somewhat less intense than the normal red, which is comparatively more yellowish, as green forms a part of it. The orange of the spectrum is again

blindness. In green-blindness the found affected by the red and by spectrum. Red and green are then by the green-blind in the same words, are to him exactly the same cases where he succeeds in distinguishing is by the aid of the intensity of with regard to this intensity of opposite of what occurs in the red-blind. A green tint which to appears exactly like a red one without sense of colour be sensibly more like red. This is shown by the dotted between R and O, in Diagram 3, and between Y and G, and is confirmed by experience.

Violet-blindness is due, according to the absence or paralysis of the perceptive violet. The two primitive violet-blind are then, according to and green; and their spectrum must be as in Diagram 4. In this condition

Fig. 4.

pure red colour, not yellowish, but still less saturated. The more towards orange, the more strongly but it is at the same time less whitish. The yellow is, as it were, of almost equal proportions of the colours which form white. Green is luminous but whitish green, which towards the blue, becomes more saturated, so that greenish blue must be these hues. The Blue is a great luminosity, and strongly saturated

wanting, is yet deficient in acuteness; and deficiency may vary greatly in degree. There are cases in which there is a deficiency of vision in respect of all colours, so that, in a chromatic representation of the state of vision of such an eye, all three of the curves would be drawn lower than the normal, although some of them would be absent. Such a condition would imply, manifestly, a diminished power of perception for white light, that being the union of the rest, and it is found in cases of so-called night blindness, the subject of which, although able to fulfil ordinary functions in the daylight, almost lose vision on the approach of dusk. There can be no difficulty in seeing that colour blindness, or rather defective colour vision of this kind, may merge gradually, as in the progress of disease, into the loss of vision.

In the perfectly healthy eye the power of distinguishing colours varies greatly with the position of the field of vision from which the colour is seen. In order to examine the lateral extent of the field of vision we use an instrument called a perimeter, of which I here exhibit the forms. The eye under examination is made to look steadily at this central point, and a second object is made to glide along a curved arc, from its termination towards its centre, and the arc is shifted from one meridian to another as required. Now the second or moving object first becomes visible in the outer parts of the field, solely by form and not at all by colour, and cannot be recognised. Its appearance depends mainly upon whether it be lighter or darker than its surroundings, and hence the colour of the object, of whatever colour, will appear as grey on a light ground, and white or black on a dark ground. As the object advances across a zone of the field of vision which is sensitive to violet, next a zone which is sensitive to red, and sensitiveness to red only commences till later period, while full sensitiveness to red of the primary colours exists only in the central portion of the retina. With a little practice, it is not difficult to hold a red object in a position that its form is still visible, while colour ceases to be distinguished.

On the basis of the foregoing facts, Professor Green has proposed to divide and classify colour blindness as follows; and his proposals have met the general assent of those engaged in the investigation of the subject:—

**Total colour-blindness**, in which the faculty of receiving colours is absolutely wanting, and the visual sense consequently can only perceive the difference between darkness and light, as in the different degrees of intensity of light. **Partial colour-blindness**, in which the faculty retains perceptions of colour, but not of all, is called defective. It is sub-divided into—

**Complete colour-blindness**, in which one of the three fundamental sensations, one of the three sensitive organs of colour in the retina, is wanting, paralysed, and in which, consequently, the visual field has but two ranges. This includes three kinds, namely:—

**Red-blindness.**

**Green-blindness.**

**Violet-blindness.**

"2. **Incomplete colour-blindness**, where one of the three kinds of elements, and perhaps all, are inferior in excitability or in numbers to those of the normal chromatic sense. Incomplete colour blindness exhibits, like the normal sense, three zones in the visual field, but is distinguished from it by an unusually small central field. This group includes the whole of a series of different forms and degrees; a part of which, comprising the superior degrees, might be called incomplete red-blindness, or incomplete green-blindness, or incomplete violet-blindness, and constitutes the transitions to the corresponding kinds of complete colour-blindness; while another part, comprising the inferior degrees, which we call a feeble chromatic sense, constitutes the transition to the normal sense of colours."

Of the varieties thus indicated, two, the complete red-blindness and the complete green-blindness, are overwhelmingly more important than all the rest, and to them, in the subsequent lectures, I shall have chiefly to direct your attention. The violet blindness is a comparatively rare condition, and, in the present state of industry, we are not aware that it is a source of harm or danger to anyone, although it may possibly sometimes be responsible for errors of colour in pictures, in decorations, and in dress. The complete forms of red and green blindness, on the contrary, have been contributory to much destruction of life and property in railway travelling and in steam navigation; and are sufficiently common to have a pressing interest for us all. I may perhaps add, in this place, that whereas there is nothing intrinsically impossible in the supposition that incomplete colour-blindness may be improved by cultivation and practice, there is great weight of evidence, as well as all analogy and probability, in support of the belief that complete colour-blindness is an unalterable condition, upon which educational efforts are simply thrown away. If there are no nerves capable of responding to a given stimulus, the mere repetition of the stimulus will have no tendency to create them.

## MISCELLANEOUS.

---

### MEMORIAL TABLETS.

In the year 1864, a letter appeared in this *Journal* (Vol. 12, p. 362) from a correspondent, who suggested that the Society of Arts should offer a prize or prizes for designs of memorial tablets to be affixed to houses associated with distinguished persons, and in the same year a series of suggested inscriptions was reprinted from the *Builder*. The subject having been brought under the notice of the Council, a committee was appointed in 1866 to consider and report how the Society might promote the erection of statues or other memorials of persons eminent in Arts, Manufactures, and Commerce; and, at the first meeting of the committee, on May 7th, Mr. George C. T. Bartley submitted some memoranda on the proposal to place labels on houses in the metropolis known to have been inhabited by celebrated persons. Subsequently, Mr. Bartley prepared an alphabetical list of names of those who were worthy of record, which was printed in several numbers of the *Journal*. In 1867, the first tablet was erected by the Society in Holles-street, Cavendish-square, on the house where Byron was born. Other tablets were soon afterwards put up,

and the erection of these memorials has been continued to the present time. In 1872, Mr. Newmarch, F.R.S., wrote a letter to the Council (see *Journal*, (Vol. 20, p. 492), suggesting certain names, some of which have been commemorated, and Mr. H. D. Pochin contributed £25 for the purpose of carrying out these suggestions. Six new ones, in commemoration of Barry, Hogarth, Newton, Peter the Great, Sheridan, and Walpole, have been erected during the present year. The complete list of tablets to the present time is as follows:—

James Barry.....	36, Castle-street, Oxford-street.
Edmund Burke .....	37, Gerrard-street, Soho.
Lord Byron .....	16, Holles-street.
George Canning .....	37, Conduit-street.
John Dryden .....	43, Gerrard-street.
Michael Faraday .....	2, Blandford-street, Portman-square.
John Flaxman .....	7, Buckingham - street, Fitzroy-square.
Benjamin Franklin .....	7, Craven-street, Strand.
David Garrick .....	5, Adelphi-terrace.
George Frederick Handel .....	25, Brook-street.
William Hogarth .....	30, Leicester-square.
Samuel Johnson .....	17, Gough-square, Fleet-street.
Napoleon III. ....	3A, King - street, St. James's.
Lord Nelson .....	147, New Bond-street.
Sir Isaac Newton .....	35, St. Martin's-street.
Peter the Great .....	15, Buckingham - street, Strand.
Sir Joshua Reynolds .....	47, Leicester-square.
Richard Brinsley Sheridan .....	14, Savile-row.
Mrs. Siddons .....	27, Upper Baker-street.
Sir Robert Walpole .....	5, Arlington-street.

The house in Leicester-square, upon which a tablet in memory of Hogarth has been erected, is occupied by Archbishop Tenison's school, for which the house was re-built. The original building, in which Hogarth lived for several years was long known as the "Sablonière Hotel." John Hunter lived next door after Hogarth's death. Of the four worthies who were intimately connected with Leicester-square, viz., Hogarth, Hunter, Newton, and Reynolds, and whose busts are now set up at the four corners of the enclosure, three will be found in the above list.

It is proposed to give in various numbers of the *Journal* representations of the houses upon which memorials have been set up, and the blocks for the four in the present number have been kindly lent by Messrs. Dawson, of the Typographic Etching Company.

The house in St. Martin's-street, which is now occupied by the schools attached to the Orange-street Chapel, is in much the same condition as when Sir Isaac Newton lived in it, from 1710 to 1727, except that the old red bricks have been covered with stucco, and an observatory on the roof has been taken away within the last few years.

Flaxman had several London residences, but the house in Buckingham-street, Fitzroy-square, is the one with which he is most intimately associated, as he lived in it during the prime of his artistic career. He went there in 1796, when he returned from Rome, and there he died in 1826, being buried in the ground adjoining old St. Pancras church, and belonging to the parish of St. Giles-in-the-fields. The house is on the south side of the street, close by Great Titchfield-street.

Canning's house, on the south side of Conduit-street, is greatly changed since the great statesman lived in it. It originally formed a wing of Trinity Chapel, which has been swept away within the last few years. This chapel was the successor of the chapel on wheels which was used at the Hounslow camp in the reign of James II., and was subsequently brought up to London. It is shown in Kip's view of old Burlington-house as

standing in the fields at the back of that house. Conduit-street was built, a chapel was erected, south side to supersede the chapel on wheels, house on the west side of the chapel, where C

NEWTON'S HOUSE, ST. MARTIN'S-STREET

lived for a time, was subsequently inhabited for years by the famous physician, Dr. Eliotson. After his death, the front was altered, and a large window made, as seen in the accompanying figs is now in the possession of Mr. Streeter, the jew

FLAXMAN'S HOUSE, BUCKINGHAM-STREET.

Dr. Johnson had so many residences in London there is some difficulty in choosing the one that is interesting to us. The house in Gough-square special claims to attention, as it was there that the lexicographer chiefly compiled his dictionary. garret, with its slanting roof, in which his son worked, and his own study are still to be seen. son himself, in his "Life of Milton," observes, "I but remark a kind of respect, perhaps uncommensurate to this great man by his biographers; every h

where he resided is historically mentioned, as if it were a duty to neglect naming any place that he honoured his presence." Emboldened by this expression of opinion, Boswell one evening, in the year 1779, ventured

CANNING'S HOUSE.

ask Johnson the names of some of his residences, and obtained the following list, which he printed in his *Life of Johnson* :—(1) Exeter-street, off Catherine-street, Strand; (2) Greenwich; (3) Woodstock-street, near Hanover-square; (4) Castle-street, Cavendish-

square, No. 6; (5) Strand; (6) Boswell-court; (7) and again; (8) Bow-street; (9) Holborn; (10) Fleet-lane; (11) Holborn again; (12) Gough-square; (13) Staple-inn; (14) Gray's-inn; (15) Inner Temple-

lane, No. 1; (16) Johnson's-court, No. 7; (17) Bolt-court, No. 8. In this last place he died in 1784.

In April, 1879, the Corporation of the City of London were asked to co-operate in this work, and to undertake the erection of suitable Memorial Tablets within the City boundaries. The matter was referred to the City Lands Committee, with which body the Secretary has had several communications with respect to the localities suggested for memorials, the result being that the committee agreed to erect such tablets within the City boundaries.

### HORTICULTURE IN ALGERIA.

Mons. V. Ch. Joly has communicated a paper on this subject to the Société d'Horticulture of Paris, of which the following is an abstract :—

The more we advance towards the north, the more we find the taste for horticulture developed, just in the same proportion as where nature does least, necessity will always render man active and industrious. Before speaking of the production of fruits, flowers, and trees, I ought to mention the great question which preoccupies Algeria, namely, the water question; without water, no vegetables, no animals, no colonisation is possible. As there is no stream with a regular course, water is a question of life and death; mere watering is of no use, it must be constant and thorough irrigation. Rain falls only during four months, consequently it is dry for the rest of the year, and this dryness prevents the cultivation of quinine, coffee, indigo, and tea.

The destruction of the forests has done here, as elsewhere, incalculable mischief, and the planting of trees is an urgent necessity. The *Eucalyptus* would render great service. In poor soil the family of the acacias offers species which, besides furnishing firewood, would give an industrial product of great value; by judicious planting in from ten to fifteen years, the climate, now very variable, would be rendered more equable, the springs would be increased, immense pasturages would be restored, and the native population now necessarily nomadic would become settled, and the European element would be more constant. The ruins so frequently met with show that the country was at one time populous, but the destruction of forests led to the destruction of animal and vegetable life. The principal trees met with in the public gardens are the date, Bourbon palm, the *Sabal*, the *Chamærops*, the *Caryota*, the *Arceuthobium*, the bamboo, the banana, the *Dracæna draco*, the yucca, the aloe, the *Agave*, besides the *Eucalyptus*, and the plane tree. These last two play a great part in the plantations of new villages, where the engineers form broad boulevards, as they there form an enclosure which rapidly protects the inhabitants against a torrid sun. The *Eucalyptus* especially is the tree of health for low and damp grounds, on account of its great power of evaporation, as well as for its resinous juices; it grows from six to ten feet in height in one year. The temperature and moisture should always be considered as from non-attention to these important factors great waste often occurs, thus the fruit trees of the temperate zone perish quickly in Algeria, while the trees of the South of France, the almond, the jujube, pomegranate, fig, and medlar, ripen two months earlier than in France, and are of the first quality.

Until now, the principal centre of horticultural production has been Algiers and its suburbs. Everywhere irrigation is applied, the water being raised by rough homely instruments, which the labourers like, as they can make and mend them themselves. Near Algiers are the gardens of Madame Roseier, about 10 acres of which are devoted to cultivation of flowers for the local market. At Bouvades, Madame Roseier has also about 13 acres of nurseries of fruit and fruit trees. At the same place

Little has been done to assist nature in the cultivation of flowers in Algeria by man. Although the winters are mild, hothouses are necessary for propagating and for protecting certain plants from the heavy winter rains, or from the summer dust. At Algiers, in the flower market, there were to be seen some cut flowers, but few or none in pots. The flowers to be seen in April were our common ones, roses, geraniums, violets, heliotropes, lilies, heartsease, and pinks. If flowers are little cultivated in Algeria for private houses, they form a considerable industry for perfumery. Thirty years ago, Mons. Simonnet, at Algiers, and Mons. Mercurin, at Chéregas, introduced into the country the planting and distillation of odoriferous plants, since which time this industry has prospered so much, that the geranium alone covers more than 1,300 acres, and furnishes more than 6,000 kilogrammes of essence. The olive, suitably grafted and cultivated, will constitute an immense fortune for the country if it is worked according to its nature; it is thought that the region suitable for it could easily furnish 700 to 800 millions of square feet, producing annually more than 300 millions of francs.

In conclusion, a few words may be mentioned about the most precious plant for Algeria, the vine, which alone is destined to renew the face of the colony. It is planted everywhere from Kabylie (which produces an abundance of table grapes) to Morocco. And this is easily explained when we remember that at the end of five years the cost of the ground, the planting, and expenses of cultivation, is repaid, in addition to a revenue of £20 to £30 the acre. The vines are planted in lines from 5 to 6½ feet apart, to facilitate labour, and a road for carts is left around the plantations. Fortunately no phylloxera has yet appeared, but the curse of the vine in Algeria is the blue fly, which has to be knocked off the vines, and burnt with lime or petroleum. The expense of carriage is the great drawback to the prosperity of Algeria, and if this were lessened, it might become one of the richest colonies in the world.

Sturges; "Progress of the Basic Bessemer Process," by Kupelweiser (Director of the Witkowitz Works). A number of excursions to works in and about the district have been arranged for the different days of the meeting.

**Crystal Palace International Electric Exhibition.**—The following announcement has appeared:—"The second of the series of international exhibitions inaugurated this year at the Crystal Palace, inaugurated this year by His Highness the Duke of Connaught will be held in December, and remain open some months. It is intended that this exhibition will be the most complete and most modern systems of electric lighting will be represented at the Crystal Palace, so that manufacturers, theatre owners, who are thinking of applying electric lighting to their factories, warehouses, theatres, &c., will have an opportunity of seeing the various systems of electric lights and judging for themselves of their local circumstances best. The first exhibition for an electric exhibition, as the same lights being seen from 4 p.m., or even to the many and various systems of electric lighting, will have a complete exhibit of 1

## AL OF THE SOCIETY OF ARTS.

No. 1,508. Vol. XXIX.

RIDAY, OCTOBER 14, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.O.*

## MEETINGS OF THE SOCIETY.

## "OWEN JONES" PRIZES, 1881.

Competition was instituted in 1878, by the Society of Arts, as trustees of the 400, presented to them by the Owen Jones Committee, being the balance of the donations to that fund, upon trust to expend the same in prizes to "Students of the Society of Art who, in annual competition, produce the best designs for Household Furniture, Wall-papers, and Hangings, Damask, &c., regulated by the principles laid down by Owen Jones." The prizes are awarded annually on the results of the annual competition of the Society of Art and Art Department.

Prizes were offered for competition in the year, each prize consisting of a bound copy of Owen Jones's "Principles of Design" and a medal.

Following is a list of the successful candidates:

- 1. Fidler, School of Art, Salisbury—Design for a lamp.
- 2. Lamb, School of Art, Kidderminster—Design for a carpet.
- 3. Dutton, School of Art, Nottingham—Design for a table.
- 4. Phillips, School of Art, Northampton—Design for a wall paper.
- 5. Harris, School of Art, Salisbury—Design for a chair.
- 6. Clulow, School of Art, Macclesfield.

## CANTOR LECTURES.

## COLOUR BLINDNESS.

By B. Brudenell Carter, F.R.C.S.

PART II.—DELIVERED MONDAY, MAY 23, 1881.

*of the colour-blind in daily life. Their means of endeavouring to counteract the consequences of their defect. Modes of testing for colour blindness. Sources of error in testing. The actual nature of the affection in this and other countries, and in different classes of the population.*

As I have mentioned, in my former lecture, to explain the nature of colour blindness, as is known of the essential nature of the defect; and I proceed to-day to describe the consequences of the defect. I may,

perhaps, first be permitted to recapitulate that what we call colour is dependent upon the varying proportions in which different substances destroy the whiteness of the solar light, by subtracting from it some of the elements of which it is composed; that the colours of all natural objects are mixtures, because there is no object which subtracts, either from white or from previously coloured light, the whole of the red, the green, or the violet which it contains; and that the essence of complete colour-blindness is an incapacity on the part of the nerves of vision to respond to the stimulus which one of these three kinds of light is calculated to produce. There is nothing more difficult, even if it be in any way possible, than to realise to ourselves, or to make plain to others by verbal definitions, the nature of sensations of which we have no experience; and hence the precise appearance of the world to the colour-blind, and the difference between their sensations and those of the colour-seeing, must to some extent remain a matter of conjecture. For the purpose of illustration, however, and in order, in the words of old South, to employ those arts by which reason is wont to supply the deficiency of the reports of sense, we may assume what is not quite the case, namely, that white light is composed of red, green, and violet in equal proportions, and that the three colours are of equal luminosity. It would seem to follow, then, that to eyes which are incapable of seeing one of the colours, one-third of the total illumination of natural objects must be extinguished; and hence that the world, to the senses of the colour-blind, must be one-third less bright—one-third less luminous—than it appears to others. It follows, also, that the sensation which we call whiteness must be unknown to the colour-blind. Whiteness is the result of the combination of all three primaries, of which the colour-blind can combine but two. We have here an excellent illustration of the errors which are introduced into the question as soon as we begin to mix up facts with nomenclature. A child, who is, say, red-blind, sees white objects, is told by his elders that they are white, takes his idea of whiteness from their appearance, and would describe them as white to others. Their appearance to him, however, is the same that would be produced to the eyes of the colour-sighted, by an admixture of equal parts of green and violet; and the effect of such an admixture would be the same to him as whiteness, and forms the nearest approach to whiteness that he is capable of seeing or imagining. In the same way, the white of the green-blind is an admixture of red and violet; and the same principle applies to every other colour which may be presented to him. In other words, the colour-blind person loses, out of every mixture, the effect which is produced upon normal eyes by the presence of the element of red, or green, or violet, as the case may be, which that mixture contains, and sees only the remaining elements. That which is invisible to him is practically non-existent for him; and hence, if we have the elements of green and violet in a colour, and no others, the red-blind and the normal sighted would derive the same sensation from them. If we then add the red, the red-blind person would perceive no difference; while, to the colour-sighted, the colour of the mixture would be entirely altered. The former, the red-blind, that is, would have no

the electric light; and, with the three colours exposed in approximately correct proportions, will set the wheel into rotation. You no longer see a broad sector of red, a broad sector of green, and a broad sector of violet, but simply a white surface. We will now abolish the red sector, filling the whole circle with green and violet, and then the rotation of the wheel will produce a mixture of those two colours, which most of us would describe as a sort of bluish grey, and which must nearly correspond with the appearance which white surfaces present to the red-blind. In like manner, we will next remove the green, leaving only red and violet, and the violet, leaving only red and green; and in each case the rotation of the wheel will produce some resemblance to the appearance presented by a white surface to the green-blind or to the violet-blind.

It seems probable that, before long, improved means of examining the conditions of colour-blind vision may be furnished to us by the discovery of persons who are colour-blind with one eye only, and who will be able to compare, under proper direction, the impressions derived from the colour-blind eye with those derived from that which is colour-sighted. Two such persons have been recently made the subject of experiment by Professor Holmgren, and no doubt others will be found when looked for, as they will be now that attention has been directed to the fact that they may exist.

Professor Holmgren's two cases were one of one-sided violet-blindness and one of one-sided red-blindness; and he thus describes the results which he has so far obtained from them.

First, the diagnosis of both eyes was carefully made. In both cases there was found a perfect, typical, partial colour-blindness of one of the eyes, the violet-blind on the left, and the red-blind on the right eye; the other eye in each had a weak colour sense, but still was so nearly normal that the principal colours were ascertained with perfect ease. A slight hesitation was shown only in dis-

colour-blind person sees only two colours. These are his two principal colours.

The principal colours in the spectrum of the red-blind person are, as to their position, red and green. Towards the red end, the red-blind has quite the same extension as the normal-eyed person, and is thus, in colour, "unshortened." Reckoning from the red end, his first fundamental colour is red, orange, and yellow. First green, a little on the other side of yellow, he sees a narrow "white" belt, from which his spectrum commences, and is continued, and more saturated, and after darker shades, over the place where greenish-blue, cyan-blue, and in the commencement of the violet, where he abruptly ends with a sharp limit, at line G. His spectrum is thus abnormally shortened. The fact that violet confuses the pigment colours, such as blue, purple and red, orange and yellowish green and grey, is itself. Respecting the tone of person's subjective fundamental colour, he said that his red is not quite the common red of the spectrum of which is something like cinnabar, clearer red, having a shade of orange same as the red towards the end of spectrum of the normal-eyed. mental colour, green, is also a clearer green than the normal eye has a shade of blue.

The two principal colours in the spectrum of the red-blind are, as to their position, red and blue. The yellow component is reckoned from the end, than the normal-eyed, about Fraunhofer's line D, over the rest of the red, orange, green, and ends in the blue-violet.

ng-Helmholtz theory. Regarded from a point of view, we should perhaps have green instead of yellow as one of the normal colours. But that yellow, and not that colour, as I have already for some supposed, does not shake the basis of that as has been shown by Fick and by myself. The tone of the red-blind person's first normal colour is not perfectly golden yellow, as for the normal eye to have a shade of yellow, perhaps best defined as citron-yellow, the lighter, and as olive-green in the shades. His other fundamental colour does not to be purely cyan-blue or indigo, but it is a blue with a perceptible shade of violet. It is called indigo-violet. Perfect clearness of theory will not perhaps be gained until we had opportunity of studying more cases of different kinds and degrees, and especially a case of perfect green-blindness. Professor Holmgren states that he is preparing a large work upon the subject, and the foregoing observations point to the possibility that our present conception of colour, and violet as the primaries may yet be required to require some modification.

Let us turn now to the actual mistakes made by a colour-blind in daily life, as consequences of the defect, we shall find these to be less numerous and more remarkable than might have been supposed inasmuch that nothing has come as a surprise to many persons than the recently acquired knowledge of the great prevalence of colour-blindness. Dalton, the chemist, was totally colour-blind; and when we hear that he said that the upper side of a laurel leaf was to him a perfect match for red sealing-wax, while the lower side was an equally good match for the colour of a red wafer, we are at first inclined to think it impossible that such a man could escape recognition, even for a single moment. He compared the colour of a florid countenance to a film of diluted ink spread over white paper, and said that blood was not unlike the colour which he heard called bottle-green. He was a member of the Society of Friends, he walked the street, with perfect complacency, in a scarlet gown of a Doctor of Civil Laws; and when asked by Whewell what it resembled, he said it was of the same colour as the leaves of the boxwoods outside the window, and that the colour which was of pink silk, was undistinguishable from sky-blue. It would be tedious to enumerate the mistakes of the same class which have been made by different colour-blind persons by different observers, and which depend, usually, upon some unexpected test being applied to them in an unusual manner. I am acquainted with a family in which the father sent his sons, then a boy of nine or ten years old, next room to fetch him a book, which he told him was of a green colour. The boy brought back a book like this (a red one), and his mistake was investigated, which disclosed that he and his brothers were red-blind. In a general way, then, the colour-blind manage to avoid mistakes, because they soon learn to supplement their defective sense by the study of other peculiar objects. Among children bred in the country, the thing which teaches a colour-blind to feel the difference between himself and other

people is, usually, the difficulty which he experiences in seeing any difference between ripe fruit or red berries and the leaves which surround them. Even here, it must be remembered, he sees a difference, although not the difference; because the colour to which he is blind presents to him a surface which is deficient in luminosity when compared with others, although he conceives it to be identical in colour. Thus, to quote an illustration from Dr. Joy Jeffries, a child hears people speak of the flowers or buds of the corn poppy as red, and of the leaves and stems as green. He does not perceive any ground for this broad distinction; but, seeing that it is made by those around him, and that he is laughed at if he is mistaken with regard to it, he sets himself to work to study carefully the appearances of the flowers and of the leaves respectively, and to fix in his memory slight differences, such as an eye capable of perceiving the great difference might easily overlook, and which will, nevertheless, represent to him the former. Thus, he notices slight differences in apparent luminosity of surface, and interprets these as being the same things which others call differences of colour. Unless he happens to be accidentally tested, like the boy of whom I have spoken, with nearly pure red or green, he may not only for a long time escape the detection of other people, but he may even remain unconscious of his own defect. It must be remembered that he sees certain things, and hears them described as red; and that the appearance which they present to him will give him his notion of what it is that other persons mean when they call things red. He may only be detected when some casual event serves to render useless all the fine distinctions which he has acquired; as when the gentleman who was travelling wrote a letter to his family, commencing and completing it at different halting-places, half of it in red ink and half in black, without being himself conscious of the difference. On this part of the subject some very pertinent remarks have been made by Dr. W. Pole, F.R.S., who is himself red-blind, and also by Professor Holmgren. Mr. Pole says:—

"The colour-blind must be very liable to associate, almost indissolubly, the true normal name of a colour with the sensation it conveys to their minds, whatever that sensation may be; and they may, therefore, be easily led to speak of that colour as if they saw it like other people, although the sensation they refer to may be really of quite a different nature to that which the name implies. A colour-blind person will be especially loth to believe that certain colours, which he hears about and talks about every hour of the day, can be invisible to him. Objects of these hues will probably present to his mind some ideas of colour, though not the true ones, and he may naturally imagine, therefore, that he does see them, and may give his description accordingly. And this sort of error is very much enhanced by the fact that it is not an easy matter to refer different tones of any one colour to the same colour sensation; so that a modification of tone, if considerable, may be easily supposed to be a different colour. I believe this difficulty is also felt by the normal-eyed; and the popular nomenclature of colours furnishes illustrations of the fact, different tones of the same colour having often different names, and being treated as separate colours. Pink and crimson, lilac and violet, are well acknowledged examples of this; and a dark shade of orange is called brown, which generally passes for a separate colour. Hence we may easily see what a great probability there is that the colour-blind may acquire the

one they have the greatest difficulty in comprehending. Hence the very general assertion by the colour-blind that they do see red, an assertion which I think has been far more readily accepted than it ought to be. Red is a more common colour than dark yellow, and hence the preference, by the colour-blind, of the former name for the common sensation. A great variety of bodies are known to be red by habit and association, and are for this reason often named correctly. My own experience is very decided on this point. It is only after long and careful investigation I have come to the conclusion that my sensations of colour are limited to blue and yellow. But, before I found this out, that is, for nearly thirty years of my life, I firmly believed that what I now know to be only differences in tone of one or the other of these were different colours; and hence I was in the habit of talking of red, crimson, scarlet, green, brown, purple, pink, orange, &c., not, of course, with the confidence of the normal-eyed, but still with a full belief that I saw them. If, therefore, at that time, any scientific man had examined me, I should have given him a description of my case, which I now, after more careful study, know would have been utterly wrong. I should have told him, among other incorrect statements, that I saw red objects of a full tone, such as vermillion, soldier's coats, &c., perfectly well; and I could, if necessary, have supported my assertion by naming correctly a great variety of bodies having this colour, which, indeed, I am in the habit of doing every day. It would have been inferred, with great appearance of truth, that I was really impressable with the red sensation; but I now see what an erroneous inference this would have been."

Another source of confusion in interpreting the descriptions of the colour-blind is the want of due appreciation of the different sensations that may be produced on their minds by modified hues of the same general colour. The normal-eyed person considers green, for example, as always green, whether it be yellow-green, blue green, or neutral green; whatever the particular "shade of green," as it is called, it still has, in his eye, the distinguishing character of greenness, which cannot be hidden or disguised by any predominance of blue or yellow

blind, in the words of Holmgren main, the same kind of light observer, but they perceive par manner. In the system accord arrange their colours, they have the normal observer; and this obliged to classify under the sar portion of the colours classec observer under different heads. this that they find resemblances or confuse others, which to the are quite different; for instance These confusions naturally surpr normal observer, who readily is arise from very great ignorance ( defective training. He ordinar there is no limit to the mistakes might make in this respect. B case; for each variety of colou laws quite as exact as those whic pressions of the normal observer person can no more accustom colours as the normal observer dc blind can see colours in the sa green-blind does, or *vice versa*.

This view of the matter, whi experience, explains to us how see colours; but, if we only res the names given to colours by we can be easily deceived. To j colour-blindness, and of the questions connected with it, it importance distinctly to obser between the manner in which person sees colours, and the man names them. The sensation is nature of the sense of colour in of the optic nerve from birth. ' contrary, is learned. It is conve upon exercise and habit. The are naturally the expressions o on the other hand, they are system of normal sight and can

try in cases where, as frequently happens, methods of exploration employed are indecisive, based upon erroneous principles. When we first think of the condition of the colour-blind, it is difficult to understand how they could be immediately detected when in the company of men endowed with normal sight; but experience shows us that they do escape. In the persons employed upon a railway, for example, who are required night and day to give attention to coloured signals, we usually find that a number of colour-blind are discovered, although defective sense had not previously been detected either by themselves or others, and the ability had correctly performed their duties. As I shall hereafter have to show, the fact of having avoided mistakes for some given period does not afford to the colour-blind signalman the greatest security for the future. His defect will eventually surely find him out, and that at the very moment when he is least suspicious of its influence. As a matter of fact, it is found that the number of colour-blind persons employed on the American railways has been diminished by the occurrence of mistakes on their parts which have been attributed to carelessness, or even to drunkenness, and which have led to their being discharged, not as colour-blind, but as bad servants. A recent American writer says that the colour-blind eliminate themselves from railway employment in this way in the course of a few years, and that they are never found among the old servants of any company. Unfortunately, in the process of eliminating themselves, they have often eliminated other people

methods for testing for colour-blindness have been adapted, it is evident, to avoid the sources of error which Messrs. Pole and Holmgren have pointed out as likely to arise from nomenclature, and to avoid those also which might arise from the unequal luminosity of the various tests, and to be equally applicable in practice to large numbers of persons. All these conditions are fulfilled by Professor Holmgren's coloured worsteds, and by these; although there are many other methods of examination which are applicable for different purposes, and especially for analysing the precise nature and degree of colour-blindness in cases in which it has been already discovered to exist. The worst conceivable test, that which on the one hand would allow a large proportion of the colour-blind to escape detection, and which, on the other, would cause persons to be set down as colour-blind who were not so in reality, is one which has been adopted, in pure ignorance, by many railway companies, who profess to test the colour-vision of those seeking employment on their lines. This test, the worst feature of which is its superficial appearance of being satisfactory and complete, consists in the exhibition of red and green lights, alternately or in irregular succession, while the candidate is called upon to name them as they appear. In order to estimate the process at its true value, it must be remembered, that a red and a green light, under similar conditions of illumination, would not look alike to a colour-blind observer, who, if he were red-blind, would see the green light as the more luminous of the two; and, if he were green-blind, would see the red light as the more luminous of the two.

Between the two lights, therefore, there would in either case be a distinctive difference of their apparent luminosity; and the person examined would manifestly have more than an even chance of being right in his guess as to which of the two was red and which was green; and would be able, if he were right the first time, to keep right all through the questioning process. An examiner who knew or suspected that the candidate was colour-blind, might be able to lead him into error if he had command of a contrivance by means of which the brightness of each lamp flame, behind the coloured glass, could be increased or diminished; but nothing of this kind has been ordinarily employed for the purpose, and it would at best be a troublesome contrivance. A man who was not colour-blind at all, but only dull, or careless, or imperfectly acquainted with the names of colours, although quite able to distinguish them, might easily call red green, or *vice versa*; and then the question would arise as to how many mistakes in the name of the exposed colour might be accepted as evidence of colour-blindness, or how many correct answers as evidence of colour vision. When thus regarded, it is manifest that the test is worthless; inasmuch as no colour-blind person would be likely to be wrong every time, and many colour-seeing people, of the class from which railway servants are chiefly taken, would be very likely to be wrong occasionally. Besides these objections, there is the further one that no test is satisfactory which rests in the least degree upon nomenclature. The object of the examination is to discover whether some given person sees colour in the same way as the majority of mankind, or in the same way as the colour-blind minority; and what the colours are called, either by the majority or by the minority, has nothing whatever to do with the real question at issue.

Now the principle of Holmgren's method of examination is to compel the colour-blind to reveal themselves by their acts, altogether without reference to their language; and for this purpose they are not asked the names of colours, but are directed, from among a large number of coloured objects, to select the tints which match or resemble certain selected patterns which are placed before them. If the persons examined are colour-sighted, they will select only the correct matches for this purpose, while, if they are colour-blind, they will make certain definite mistakes which will disclose the precise nature as well as the existence of their defect, and which could be predicted by any who were previously aware of it. A person who was only careless, or a person who, if such a thing could be conceived, was simulating colour-blindness from mischief or from some other motive, but without adequate knowledge, would, so to speak, make the wrong mistakes, and would thus betray himself at once to a competent examiner.

For the purposes of such an examination, almost any coloured substances might be employed; but skeins of Berlin wool are found to present many practical advantages. They are cheap, easily handled, easily obtainable in every variety of tint, and therefore easily replaced when soiled or injured. Holmgren's full collection consists of about one hundred and fifty skeins, including red, orange,

a piece of worsted work, arranged by Dr. Dane, in which, on some of the lines, the colours which are liable to be confounded are placed in juxtaposition. The objection to all schemes of this kind is that the colour-blind have to be asked questions about a sorting which has been already performed by others; while, in the Holmgren method, they reveal themselves with much greater rapidity and certainty when engaged in accomplishing the sorting for themselves.

The time at my disposal does not allow me to repeat the reasons, partly theoretical and partly derived from experience, which have guided Professor Holmgren in the selection of his sample colours; and it is sufficient to say that these are light green, purple, and bright red.

In conducting the examination, the worsteds are placed on a large table, in broad daylight, and on a white cloth. A skein of the test colour is picked out by the examiner, and is laid down at a short distance from the pile. The person examined is then directed to select from the pile the other skeins which resemble the sample in colour, and to place them by the side of the sample. The examiner should first do this himself, and then mix the skeins again, so as to show the examined exactly what is required from him; and, when a large number are to be examined, the instruction should be communicated to all at once, and then each should step forward singly and in turn to make his or her selection. In this way about a minute will suffice for each individual.

The colours which are exhibited on the screen before you, and which are taken from Holmgren's work, are intended to show the nature of the mistakes which exhibit colour-blindness. The plate does not exhaust these mistakes, and shows only those which are most characteristic. The test colours are arranged horizontally; while the colours of confusion, or those which the colour-blind are liable to confound with the former, are arranged vertically beneath them.

In the first place, the green sample is presented

together. The examination is with this second sample until the has placed near to it all or the skeins of the same shade, or all or separately, one or several skeins. He who confuses the colours will select light or deep shades of blue as the deep; or the light or deep of green or grey inclining to purple, red, and orange, indistinctly.

He who is colour-blind by the in the second, selects only purple or green-blind.

He who, in the second test, selects only blue and violet, or one of red-blind.

He who, in the second test, selects only green and grey, or one of green-blind.

He who, in the second test, mixes with the purple, is completely colour-blind.

The red-blind never selects the green-blind, or vice versa; and in a simple manner, evidence is given of the two defects.

With this second test, the examination is concluded; and it is not even necessary to decide whether the blind is green. But to be more complete in the relation of colour-blindness to colours, and especially in order necessary, railway authorities are not experts, the examination may be one more trial, which should be completely colour-blind, and necessary to the diagnosis, but which corroborate the results of the previous. For this purpose, a vivid red skein of a red rather inclining towards resembling the red used for signal should then be continued until selected all the skeins belonging to the greater part of them, or else

A practical difficulty will sometimes be the case of incomplete red or green-blindness the examiner may be asked whether a person is red-blind or green-blind enough to be a source of danger to himself or others. We have to deal with a question of degree only; which the expert can do is to reduce the incomplete colour-blindness to numerical facts. When this has been done, it will be in the authorities to draw the line of safety.

For this purpose, it must be assumed that a normal-eyed person will distinguish the colour of an object at some stated distance; and it follows that the incompletely colour-blind, who can make no such distinction by means of a normal impression upon their nerves of sight, must approach nearer before they can speak with any certainty. Hence, the distance of colour vision for the normal-eyed being taken as a standard, the distance of colour vision in the incompletely colour-blind affords at once a numerical estimate of their defect. If the normal-eyed can distinguish between red and green at ten feet, and the red-blind only at five feet, with objects of the same magnitude, and with light of the same intensity, the latter may be said to be one-half of the normal acuteness of colour vision. In order to determine the point, Holmgren has devised an apparatus so contrived as to cast shadows, the intensity of which can be varied at will; but perhaps the best contrivance for this purpose is that of Professor Donders, or an improvement of it by Mr. Nettleship. In Professor Donders's lantern, which carries a pair of glass discs, so arranged as to display, under examination, a circle of either red, or green light of larger or smaller sizes; found in practice that, whereas the normal-eyed distinguish colour as soon, or nearly as soon, as they can distinguish the light, the incompletely colour-blind have to approach much nearer, and shown a much larger circle, before they can arrive at the same decision with any certainty. In Mr. Nettleship's lantern, two circles of different colours can be shown simultaneously and side by side with both of these contrivances a number of interesting trials may be made.

It is still to speak of the relative frequency of colour-blindness in this and other countries, and of the different classes of the population; and on this point it is only quite lately, since Holmgren's method of examination has been understood and adopted, that any trustworthy statistics have been obtained.

Examinations of earlier times, under which colours were held up, and the persons examined were desired to name them, must be dismissed as untrustworthy; and, of all those made at times, I should place most reliance upon that of Professor Holmgren himself, and that of Dr. Joy Jeffries, in America. It is remembered, that all examinations of numbers are apt to be misleading as guides to the truth, because colour-blindness has a marked tendency, so that it constantly affects members of the same family, who, if they be collected in the same school, or within the same locality, may easily fall into the hands of the same examiner, and so vitiate the numerical results when these are taken as tests

of the amount of colour-blindness in the total population. Professor Holmgren examined 32,155 male persons, described as scholars and children of different ages, young people, railroad employees, sailors, soldiers, mill hands, prisoners, and guards, and among these he found 1,037 colour-blind, or a fraction more than 3·25 per cent. Dr. Jeffries examined in New England 10,387 teachers and scholars, and found 431 colour-blind, or 4·149 per cent. In other countries, excepting for occasional results, showing much greater numbers, and where some error has probably crept in, the results are practically much the same, and in all countries the per-centage of colour-blindness is very much smaller among females than among males. Thus, among 7,119 females of all ages, Holmgren found 19 colour-blind, or 0·26 per cent., and Jeffries, among 7,942 female teachers and scholars, found only 4 colour-blind, or 0·52 per cent.

Until the present year, nothing has been known of the actual prevalence of colour-blindness in England, although Wilson, who wrote in 1854, pointed out its frequency, and asserted that it was more frequent among the Society of Friends, and also among the Jewish community than in the general population of the country. In the course of last winter, the Ophthalmological Society of London appointed a committee to inquire into the prevalence of various defects of vision, among which colour-blindness occupied a prominent place; and that committee, of which I have the honour to be a member, made arrangements for testing the colour-vision of the Metropolitan Police, of some of the household troops, and of pupils at various schools. By the indefatigable industry of our honorary secretary, Dr. Brailey, seconded by a large number of gentlemen who gave up the requisite time to the work, no less than 18,088 persons were examined by Holmgren's method in the course of five months. Of these, 16,431 were males, and 1,657 were females. Certain classes of people were especially examined, in the expectation that they would furnish a larger proportion of colour-blinds than the general population. Omitting these classes, we have 14,846 males, with 4·76 per cent. of persons with colour defect, and 489 females, with 0·4 per cent., so that in this country the colour-blind females are only one-tenth the number of the colour-blind males. In fact, the rarity of colour-blindness among women renders them less indulgent towards it than they are towards any other distinctive male weakness; and one of the examiners told me that, in his experience, the first impulse of a mother, when she saw her son picking up a drab to go with a green, or a chocolate with a purple, was to box his ears. I have myself found the impossibility of keeping a mother quiet in such circumstances, and have been compelled to ask her to withdraw into another room until I had satisfied myself upon the point at issue.

The above-stated per centage of 4·67 includes the incompletely colour-blind as well as the complete cases, and the former alone would amount to something like 3·5 per cent. If we confine ourselves to these, and compare the results with those afforded by the selected classes, namely, the members of the Society of Friends, the Jewish community, and the inmates of deaf and dumb asylums, we find that complete colour blindness among the Friends

the possible increased light and safety over the methods hitherto adopted economy and an increased output of expense on labour.

Again, a general and public is awakened in this country when any even attempted to be done, for the creatures, and more especially when directed in aid of our helpless brethren morning to night, and night to morning dark and dismal bowels of the earth, to us more fortunate beings with the means ourselves with coal for our comfort, and

In attempting, therefore, to place of the leading mechanical and electrical case, I hope to be able to interest you and to express a desire that the remainder of the discussion may assist materially in perfecting electric lighting for coal mine

In the first place, I shall review the already done at the Pleasley and I with an account of the apparatus used in the experiments carried out, and, finally, with what appears to me the simplest and best means for fitting up a colliery

**Pleasley Colliery.**—In June last, Me ton and Co., in conjunction with the Swan Company, laid down at Pleasley Colliery an arrangement of engine, boiler, 4 leads, lamps, &c., which they placed the Royal Commissioners for Mines in suitability of the Swan lamp, as a man up the shaft bottom, roadways, and coal mines.

The large drawing on the wall gives of the complete system as carried out at the Colliery, near Glasgow, by Messrs. I. & J. Watson, the proprietors. It is from a scale drawing, kindly furnished by Mr. Gilchrist, manager of the mine.

**Earnock Colliery.**—The engine is placed about 260 yards from the engine is 12 N. horse-power, const Shanks, of Arbroath, having their (about one-third of this power being the present installation). A coun

**By Andrew Jamieson**

and insulated with gutta-percha, taped and tarred, whole being enclosed in a galvanised iron tube. The same description and size of main leading wire is followed along the whole distance of the seam to the working faces, a complete distance of 750 yards from pit-bottom, making the entire distance from the exciter to the extreme lamp 1,664 yards, or say 3,128 ft. of main leading wire. At each of the twenty-two positions shown in the figure is joined up by branch to a Swan lamp, encased in a suitable lantern, sixteen of these being fixed lamps, and six portable. The lamps containing Swan's lamps were described, they were made from the design of Messrs. D. and G. Swan. Each of the twenty-two lamps was provided with an air-tight gravity mercurial contact for the purpose of switching on and off the current. They were similar in this respect, that upon cutting a lamp out of the circuit they bring into circuit a wire resistance equivalent to that of the lamp. The primary object of these light makers or switches is to prevent the spark which is inevitably generated when opening an electric circuit from communicating with and exploding the gas in the mine. Several forms of such air-tight makers have been designed by the author in order to prevent the spark when joining up a lamp or lead. The principle upon which the lamps were arranged is that of "parallel circuit." This system of joining the lamps is neither the best nor the most economical that can be arranged. It necessitates their being nearly uniform resistance, or of slightly decreasing resistance in proportion to their distance along the main line, in order that the current may be uniformly distributed among the lamps, and thus give to each lamp its full illuminating power.

It may not be out of place here to mention that a Swan lamp has a resistance when incandescent (100-candle power), of 30 ohms, with an E.M.F. of a voltage of potential on its terminals of 45 volts, and, therefore, a current of 1.5 weber passing through it. It is slightly over 220 candles per h.p. absorbed by the lamp. The author has ascertained by actual tests made out by himself in Glasgow, from a mean of several lamps tested, that:—

E. M. F. (volts)	Current (webers)	Candle power	Candles per h.-p.	H.-P. per lamp
45	1.7	18	175	1

Of course it must be clearly borne in mind that the greater the candle-power at which the lamps are worked the greater the (horse-power) economy. If a Swan lamp were raised to a temperature sufficient to give 600 candles, then we should have about 1,200 candles per horse-power. On an average we may consider it a safe statement that ten Swan lamps absorb one-horse power. It does not take into consideration the fact that a certain amount of power is absorbed in the engine, generator, leads, &c., and in making an installation of fifty Swan lamps we may reckon 30 per cent. at least of the power as lost in the manner indicated, which leaves seven lamps per indicated horse-power, or will require seven indicated horse-power for fifty lamps, giving eighteen-candle power each.

It is important to note that the system adopted at Arncliffe Colliery is far from being the best for Swan's lamps, in as far as the self-exciting Gramme machine does not readily admit of any automatic current regulation. For example, if under ordinary circumstances we have twenty-two lamps in action, and it be desired suddenly to cut out any number of these, say ten or eleven, the immediate effect will be that of overstraining the remaining lamps by excessive currents. At Arncliffe Colliery, however, an attempt has been made to avoid this danger by causing any switch to introduce resistance equivalent to that of the lamp which it cuts

out. It will at once be seen that this is an uneconomical expedient, because the resistance thus introduced absorbs power equal to that previously absorbed by the lamp now cut out. If a Siemens's alternate current machine (with separate exciter for magnets) be used, then the E.M.F. remains practically constant whatever change is made in the number of lamps in circuit, and thus without any direct current regulator the lamps are never endangered.

This is a very great improvement upon the self-exciting Gramme or Siemens machine, and entirely does away with the necessity for a specially constructed system of automatic current regulator. It, therefore, simplifies the mechanical arrangements, and does away with the danger and inconveniences arising from turning off or putting on a number of lamps (within the limits of the machine).

These alternate current machines of Siemens also admit of burning an arc light in conjunction with and fed from the same machine as the Swan incandescent lamps; this is advantageous for surface lighting.

I cannot do better than indicate how I would propose to carry out a system of electric lighting for colliery purposes than by reviewing what I have purposed, with Mr. Swan's concurrence and approval, for Eppleton and Houghton pits, near Hetton, Durham.

1. The motive power to be Marshall and Sons best made horizontal engines, with their specially constructed automatic governor.

2. Siemens's exciter and alternate current machines.

3. Leading wire by Silvertown India-rubber and Gutta-percha Company, No. 1,092, having resistance of less than  $\frac{1}{2}$  ohm per 1,000 yards.

4. Swan's lamps encased in specially-designed strong lanterns. Those that are fixed to have hemispherical glass globes and copper-silvered reflectors, suited for projecting the lights downwards or along the gallery or seam as desired; and those that are movable to be placed in lanterns like one or other of those before you, only lighter or more handy, specially strong 100-candle power Swan lamps being provided for the screens and other places where a strong light is desired.

5. For the open space surface works, and where the railway and surface haulage takes place, Siemens's (alternate current) arc lights are proposed, suitably placed to admit of working at night with a readiness and celerity almost equal to that in the day time.

6. Ayrton and Perry's electro dynamometers for measuring the strength of the electric current.

7. Velocimeter, switches, &c., as per specification.

The complete specification and estimate is drawn up with a view of entirely superseding gas and oil on the surface works, the three coal seams, and for stables and haulage near shaft, but not to be continued to the front at present, the distance being very great (two to three miles).

[At the same meeting Mr. Swan showed a miner's lamp, in which one of his incandescent lamps was combined with a small Faure accumulator, so that it could be charged, say, at the pit's mouth, and then entirely disconnected. By this means the lamp was rendered portable. Mr. Swan stated that this arrangement gave light for about six hours.]

## NEW TOWN AT WAYNE, UNITED STATES.

The following account of a new town, for 3,000 inhabitants, to be built by Messrs. George W. Childs, of the *Public Ledger*, and A. J. Drexel, banker, is taken from an American paper:—

"Within a period of three years, the real estate along the line of the Pennsylvania Railroad has appreciated in value to the extent of 18,000,000 dollars. The first step in this extraordinary development was made ten years ago, when the Pennsylvania Railroad Company

bought 600 acres of land near White Hall, changed the line, named the new station Bryn Mawr, divided it into building lots, and sold it under such restrictions as to attract the wealthiest classes of the community to that station. It was about a year ago that Messrs. Childs and Drexel bought 600 acres of land, at Wayne Station, for 340,000 dollars, the tract having a frontage of a mile and a-half on Lancaster avenue, and on the railroad. It is the purpose of these gentlemen to divide the land into building lots of about an acre each, to erect artistic cottages, ranging in price from 2,000 dollars to 8,000 dollars, and to dispose of the houses and lots upon payment of about one-third the cost, Messrs. Childs and Drexel advancing two-thirds, thus affording to folks in moderate circumstances an opportunity of securing suburban residences upon reasonable terms. Within two minutes' walk of the new station, Mr. Childs has built the Bellevue Hotel, an ornate drab structure, in Queen Anne style, with porches on every side, which rise in tiers to the fourth floor. At the lower end of the tract another hotel, to be called the "Audubon," and capable of accommodating 150 guests, will be erected. Surrounding these properties and on Lancaster avenue will be five hundred residences, laid out on avenues having a uniform width of 60 feet, and footways from 12 to 16 feet wide. The houses recede 40 feet from the line of the avenue. Ornamental trees will be planted on either side. The roadway will be macadamized, and, with the forty-foot lawn between the house line and the footway, there will be a width of 170 feet between buildings on opposite sides of the avenue. To improve the landscape, Mr. Charles Miller, the chief of the Horticultural Department at the Centennial Exhibition the Fairmount-park gardener, and the designer of the beautiful grounds at Wootton, Mr. Childs's country residence, has been engaged. The drainage system is under the supervision of Colonel George F. Waring, the sanitary engineer, whose advice was sought lately regarding the condition of the Executive Mansion at Washington. The water supply system, devised by Mr. Isaac S. Caswin, is now complete. It will supply a population of 20,000 people. The reservoir, covering nearly an acre of ground, and holding 250,000 gallons of water, is located on a knoll at the western end of the tract, at an elevation of 450 feet above tide-water, giving a head of 82 feet. The water is supplied by springs, and is pumped from a pretty lake, where the flow of Ithan Creek is retained. More than two miles of six-inch distributing mains have been laid along the various avenues, the water works have been in practical operation for seven weeks, and everything is in shape to make connection when the buildings have been erected. At a short distance west of the Childs-Drexel property was the Spread Eagle Hotel property, a well-known stopping place on the Conestoga-road, where liquors were sold. This property was purchased by the two capitalists in order that no spirituous liquors might be sold near the site of their new city.

## GENERAL NOTES.

**Howard Medal Essays.**—The Council of the Statistical Society have again decided to grant the sum of £20 to the writer who may gain the "Howard Medal" in November, 1882. The essays to be sent in on or before 30th June, 1882. The subject is—"On the State of the Prisons of England and Wales in the Eighteenth Century, and its Influence on the Severity and Spread of Small-pox among the English population at that period." The essays also to present a comparison of the mortality by small-pox among the prison population of England and Wales during the eighteenth century, with the mortality from the same cause during the last twenty years. Further particulars or explanations

may be obtained from the Assistant Secretary, at the office of the Society, King's College Entrance, Strand, W. London.

**School of Art Wood-carving.**—The School of Art Wood-carving has re-opened after the usual summer vacation. Free studentships in both the day classes and the evening classes are at present vacant. These studentships are maintained out of funds provided by the City and Guilds of London Institute for the Advancement of Technical Education. The necessary information, with forms of application and prospectuses of the school, may be obtained by letter, addressed to the Secretary, School of Art Wood-carving, Royal Albert Hall, Kensington, S.W.

**Melting Steel.**—On Tuesday, October 11th, the members of the Iron and Steel Institute visited the Telegraph Construction Works of Messrs. Siemens Brothers & Charlton, on which occasion Dr. Siemens, F.R.S., exhibited his experiment of melting steel by means of the dynamo-electric current, when five pounds of steel were melted in five-and-twenty minutes. The apparatus comprised a set of an ordinary crucible of plumbago, or other highly refractory material, placed in a metallic jacket, or casting, the intervening space being filled up with sand charcoal, or other bad conductor of heat. A hole is bored through the bottom of a crucible for the admission of air of iron platinum or dense carbon, and the cover of the crucible is placed for the reception of the negative electrode, which is suspended at one end of a beam by means of a strip of copper. The other end of the beam is attached to a hollow cylinder of soft iron, free to move vertically with a wire coiled, one end of which is connected with the positive, and the other with the negative pole, of the dynamo arc.

**Anderson's College.**—Dr. Mills, F.R.S., "Tong" Professor of Technical Chemistry at Anderson's College, Glasgow, has issued a syllabus for the session 1881-82. A course of fifty lectures will be delivered on Monday Tuesdays, and Wednesdays, at 10 a.m., commencing on November 7th. The lectures will be illustrated with experiments, diagrams, and models, as well as by the actual inspection of manufacturing processes, and the progress the students will be tested by periodical examinations. In earlier lectures will have reference to units of weight and measure, to the calculations necessitated by chemical equations, and to the nature and laws both of the chemical process and its results. A particular subject will then be considered in comparatively minute detail, embracing in this session dyeing and printing. A subsequent course of thirty lectures will be delivered, which are more particularly intended for dyers, colour manufacturers, brewers and distillers, tar rectifiers, drydistillers, and others interested in knowledge of technical organic chemistry. Mr. J. Sanderson, senior assistant, has arranged to deliver a series of six lectures and demonstrations on physico-chemical measurements, and also a course of evening lectures on coal and coal manufacture, in time for the May examination.

**Ladies' Sanitary Association.**—A Second Series of nine lectures on "Domestic Sanitation" will be delivered by Dr. Richardson, F.R.S., in the Lower-hall, Royal Albert Strand, during October, November, and December. In the course of lectures the structure and functions of the nervous system of man will be presented. The physical and mental training of the young will be considered in the division. The lectures will be illustrated by the apparatus hydrogen lantern. The first lecture will be delivered on Saturday, October 22nd, at 5 p.m., and will be continued following Saturdays until December 17th. Tickets for the Course, one guinea (transferable). Single tickets, seven shillings, 6s., may be obtained of the Secretary, Miss Ada Adams, at the office of the association, 22, Grosvenor W. Unreserved seats, 1s., by payment at the door. 50 prizes will be awarded to the most proficient students as follows:—First Morley Prize of Ten Guineas, and Second Morley Prize of Five Guineas, given by Mr. Lord Morley, M.P.; Prize of Three Guineas, given by Mr. Marshall; Prize of Two Guineas, given by Mrs. Sturges; Prize of One Guinea, given by Lady Mount-Temple; Prize of One Pound, "Competition," given by Mr. W. Phillips. Certificates of first and second-class merit will also be awarded.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,509. VOL. XXIX.

FRIDAY, OCTOBER 21, 1881.

Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.

## PROCEEDINGS OF THE SOCIETY.

## CANTOR LECTURES.

## COLOUR BLINDNESS.

By E. Brudenell Carter, F.R.C.S.

III.—DELIVERED MONDAY, MAY 30, 1881.

is chiefly affected by colour-blindness—  
-drivers, pilots, artists, letter-sorters,  
, painters, &c., &c. Recent legislation  
g colour-blindness in America, and urgent  
r it in this country. Conclusion.

course of the two preceding lectures, I  
endeavoured to show that the sense of colour  
upon the nature of the light which is  
derived from visible objects, and that what is  
colour-blindness depends upon want of  
ness, on the part of the optic nerve, to per-  
agnitudes of wave vibration, so that the  
nsations which these vibrations excite in  
yes are not perceived, and the correspond-  
ing rays are invisible, and are lost out of all the  
rays into which they normally enter. Thus,  
light at what we call purple, which is a mix-  
ed red and violet, the person who is blind to  
it only its violet element, and selects  
violet to be a match with it. The red-  
blind, in a similar manner, loses the red element  
of colours or mixtures of colours, and the  
red-blind loses the green element; while, to  
the latter, the difference between red and  
violet is imperceptible, except as a difference of  
brightness or luminosity; green appearing the  
brighter of the two to the red-blind, and red to  
the green-blind. In the case of persons who are  
totally red-blind, or incompletely green-  
blind, the difference between the two colours is  
recognised as a difference of luminosity at a  
distance, and becomes recognised as a difference of  
brightness at a nearer approach; the precise point at  
which the difference of colour becomes apparent  
for equal luminosities, very widely in  
different cases, and furnishing a measure of the  
degree of the defect.

I have already mentioned that there are a few  
cases of total colour-blindness, or of people who  
are blind to all but form and light and shade, but  
who are also blind to violet, are of such rare  
occurrence, that practically they scarcely call for  
attention. My chief business to-night is to  
be dealing with the bearing of red-blindness or of green-

blindness, either complete or incomplete, upon the  
fitness of the subjects of these defects to engage in  
certain industries, of which those which call for  
the recognition of railway and marine signals are  
the chief.

If we take as an illustration, in the first instance,  
the state of an engine driver who is completely  
red-blind, and who is called upon to govern the  
course of a locomotive in obedience to certain  
coloured signals, which may be either red and  
green alone, or white and red and green, in accord-  
ance with the regulations of different roads, we  
find that these signals present to him differences  
by which, in many cases, he can tell them apart;  
but these differences are of brightness, or lumi-  
nosity, and not of colour. From the white light  
he receives the whole of its green and violet, the  
red being lost to him, so that what he sees is a  
blue gray, comparatively feeble in brightness when  
contrasted with the impression made by the same  
light upon a normal eye. The green light will be  
removed still farther from the brightness by reason  
of its preponderance of green, and the red will only  
be visible by means of the rays other than red  
which the red glass transmits, and if nothing but  
red was transmitted, would be invisible altogether,  
so as to be what an Irishman might perhaps call a  
dark light. For practical purposes, however, we  
may omit the white lights from consideration, and  
may fix our attention only upon the red and green.  
Of these, the former, to a red-blind man, would  
seem darker than the latter; and this reflection  
would be reversed in the case of a green-blind.  
We may perfectly well suppose the colour-blind  
person, in either case, to be unconscious of his  
defect. He has all his life been accustomed to in-  
terpret the phrase "a red light" as meaning  
something which presents to him a dim or feeble  
illumination, and to interpret the phrase "a green  
light" as something which presents to him a  
stronger or brighter illumination. By the help of  
this distinction, he may pass an examination which  
is inadequately conducted, and he may drive his  
engine for long periods without accident or mis-  
take. But the point at issue is that he is com-  
pelled to rely upon an unreal distinction, a distinc-  
tion of relative brightness only; and that his judg-  
ment upon this relative brightness is liable to be  
misled by accidental circumstances. Anything  
which increased the apparent brightness of the red  
light, as, for instance, a better burning, or even  
a quite recently lighted lamp, a red glass of less  
thickness or slightly different tone, or of less ab-  
sorbing power than usual, these and many other  
other possible variations would lead him to mistake  
a red light for a green one. In the same way,  
anything which diminished the apparent bright-  
ness of a green light, as a thicker or more absorb-  
ing glass, a badly burning lamp, the intervention  
of steam, smoke, or fog, would render him liable to  
commit the comparatively harmless mistake of  
taking a green light for a red one. To the green-  
blind, on the other hand, the reverse conditions  
would obtain. To him, the green light would be  
comparatively dim, and the red one comparatively  
bright; so that any of the conditions which would  
brighten the red light and make it more conspicuous  
to the normal sighted, would render it more like  
green to the green-blind, and would directly serve  
to tempt him into danger. It has been well

observed by Dr. Joy Jeffries that no right minded and conscientious person would undertake the guidance of a train, on the announced condition that, in any variations of atmosphere and weather, he was to recognise a dim light as a danger signal, and a bright light as a safety signal, and *vice versa*, and that his own life, and the lives of the passengers, were to be dependent upon his always rightly determining which was which.

It has often been maintained that we hear very little of accidents actually arising from colour-blindness; but it must be remembered that, until quite lately, this cause of neglect or mistake of signals was scarcely recognised by those whose duty it is to investigate such occurrences. At the present day, the first inquiry which would be made, in any case of over-running a danger signal, would have reference to the colour vision of the man in charge of the engine; but, even so lately as two years ago, the point would have been likely to be wholly overlooked. Admitting, as must no doubt be done, that the calling of an engine driver affords no immunity from colour-blindness, and that the colour-blind engaged in it, in default of measures for their discovery and rejection, are in the ordinary proportion of from four to six per cent., it is almost assuming a miracle if we say that accidents have not happened from conditions apparently certain to produce them.

The latest statistics of the examination of persons employed on railways with which I am acquainted are those collected by Dr. Joy Jeffries; and, in estimating their significance, it is necessary to remember what I mentioned in a previous lecture, that colour-blind railway servants have a tendency to eliminate themselves from their situations, by mistakes which do not lead to accidents, but which are noticed by their superiors, and are set down to drunkenness or carelessness, and held to require dismissal. Notwithstanding this:—

Dr. Hansen, a distinguished ophthalmic surgeon of Copenhagen, of whom I may observe in passing that my personal knowledge of him would lead me to place implicit reliance in the accuracy of his observations, states that among 1,034 railway servants in Denmark, there were 31 colour-blind, or 2·87 per cent.

Dr. Stilling, of Cassel, reports 24 colour-blind among 400 railway servants, or 6 per cent.

Dr. Magnus, of Breslau, reports four per cent. among railway servants tested by one of his colleagues, but does not give the total number examined.

Professor Donders, of Utrecht, with the assistance of Dr. Bouvin, examined 2,203 of the *employés* on the Dutch railroads, and found 152 colour-blind, or 6·9 per cent.

Dr. Von Reuss found 3·50 per cent. of colour-blind among 800 *employés* of one of the Vienna roads.

In the Swedish army, Professor Holmgren found 60 colour-blind among 2,200 men, or 2·7 per cent., and used this fact as a means of obtaining an examination of the railway servants throughout the country. In the first 286 men tested, there were 13 colour-blind, or 4·8 per cent., and the Professor has since examined 7,953, among whom there were 171 colour-blind, or 2·15 per cent. In Finland, there were 60 colour-blind among 1,200 railway servants, or 5·0 per cent.,

the examination being conducted by Dr. L. Krohn, after instruction by Professor Holmgren in his method. Nearly the whole of these examinations were conducted in the latter part of 1877; and they show that at that time, in the comparatively small amount of mileage and extent of country which they cover, there were no less than 479 colour-blind persons engaged in the actual conduct of railway traffic. These figures include all sorts of people, drivers, stokers, pointmen, porters, and the like, for many of whom, in their ordinary occupations, their defect might not be a source of danger, but who would be liable, in all probability, to be concerned in signalling or in obeying signals, at least sometimes. It is a significant fact that some among them were station-masters.

Dr. Joy Jeffries quotes from Dr. Minder, of Berne, a narrative which is of sufficient interest to be repeated. Among Dr. Minder's cases was that of "a very intelligent young man who was blind, but was not aware of it. He held the position first of stoker, and then of driver on one of the Swiss roads. He was hardly at work before his defect troubled him. Thinking it was due to the spirit he drank, he stopped this for a while; but, the trouble continuing, he became convinced that 'something was wrong with him about the colours,' and left the recognition of the signals to his normal-sighted assistant. When another man, who seems also to have been colour-blind, took this assistant's place, the work began to be 'uncomfortable.' The red-blind driver had no one to correct him; and, as he was very frequently mistaken in his conclusions, there occurred a series of mistakes, fortunately only while manoeuvring at stations, which brought upon him occasional fines and other disagreeable consequences.

"The red signal lantern gave him the most trouble, because, as he said, he could only distinguish it when so near with his engine as not to be able to stop, and hence often ran by it. He did better with the green signal; and, when asked why, replied, 'because it was brighter.' To the question how, then, could he tell the green signal from white, he, in a roundabout way, compared green to weak white; and stated that, with a lantern of white glass, he could, by screwing the wick up and down, and thereby changing the amount of light, himself imitate the usual railway signals. Very bright light was white; very weak light, red; medium intensity, green—in complete correspondence with the statements based by Holmgren upon the Young-Helmholtz theory. The apparent impossibility of his power of distinguishing between the lights being dependent only on their relative intensities induced me to search farther, and to ascertain what a complete colour-blind understood by pure white. A whole series of colour-blind persons were expressly asked to select only the purest white from among the test objects presented to them. Of worsteds and papers they picked out, besides the white, several shades of bright green, gray, pure gray and dirty gray, light rose, and very light violet." This entirely corresponds, it will be observed, with the illustration of the appearance of white to the colour-blind which was given by means of revolving discs in my last lecture, and which we will repeat on the present occasion.

In my first lecture I mentioned as a matter of probability, and was misreported in some papers as having stated as a fact, that there are in the United Kingdom more than 400 colour-blind engine drivers. As far as I am aware, the facts have not been ascertained, and my statement was based upon these grounds. According to the Board of Trade returns, the locomotives in use in the United Kingdom during the year 1879 were 13,174. There is no information with regard to the number of these which were in actual running order; but the statistics of the South-Eastern Railway, for the successive half-years between June, 1875, and December, 1879, show an average of 73·3 per cent. of the locomotives as running at any given time, while 26·7 per cent. were in the shops under repair. On the basis of these figures, kindly furnished to me by Mr. Price Williams, I assume that, of the above-mentioned 13,174 locomotives, 70·0 per cent., or 9,222, were always in running order, and were therefore giving employment to the same number of drivers. I assume farther that, among these 9,222 engine drivers, little or nothing having been done to weed out the colour-blind, there will be the same proportion of this defect which has been recently discovered in the Metropolitan Police, or 4·67 per cent. This percentage, upon the number stated, would give a total of 424 colour-blind men.

The question may here be fairly asked, whether it is true that little or nothing has been done to weed out the colour-blind from such an employment as engine-driving; and I fear there can be no doubt that the answer must be in the affirmative. I do not know of any official returns upon the point, and I have been told that some companies have instituted an examination into the colour-vision of their servants, and of all candidates for employment. This is no doubt highly satisfactory as far as it goes, and may at least lead to effectual precautions in the future, but there is no evidence that it has accomplished anything at present. The subject is a new one; or rather, as I have already stated, it is one which has only recently emerged from the position of a matter of scientific curiosity into that of a matter of practical importance. The attitude of mind of railway authorities with regard to it was, in the first instance, that attitude of passive resistance which the human mind is so apt to assume in the presence of suggestions for improvement. It is a familiar saying that people meet every discovery by first saying that it isn't true, then that it isn't new, next, that they have always known it. Now the first suggestions that colour-blindness was a common affection, and a source of actual peril in railway working, were met with absolute denial and entire incredulity. As soon as the railway authorities were driven from this first line of defence, some of them said "well, we will institute examinations." At this stage they seem to have believed, I think not unnaturally, that the question was a very simple one, which anybody was competent to decide; and the result of this was that they committed the examinations to the hands of incompetent persons, who used methods which, as I showed in a previous lecture, were not only valueless, but misleading. The truth is, that the testing of colour-vision, in a way to be at once fair to the employers and to the servants, is a matter

which requires very considerable practical experience not only of this particular defect, but also of the methods of testing vision generally. I believe it to be impossible for any but experts to conduct the examination of a large number of men at once with correctness and with accuracy, and I have no doubt that serious errors have been committed from the want of recognition of this fact. I may be pardoned for pointing out that even the medical officers of a line of railway, whose ordinary duties have little or no relation to vision, are not always experts with regard to it; while the examiner often employed, some worthy person who has been promoted from being a porter to be an inspector, would be sure to blunder in every direction, and, in the rashness of pure ignorance, would constantly decide upon inadequate grounds. I have heard, although I do not vouch for the truth of the statement, that the examiner employed upon one line of railway, was himself, after he had been for some time engaged in the duty, accidentally discovered to be colour-blind; and it is astonishing how few persons, even of fair education and ordinary intelligence, are at first able to emancipate themselves from the confusion incidental to the correct or incorrect use of colour-names, which, as I have already pointed out, have no necessary connection with colour-vision. In the report drawn up by Dr. Brailey, for the committee of the Ophthalmological Society, from which I have already quoted the statistics of colour-blindness in England, I find the following passage, which is based upon his observation of the examination of more than 18,000 persons, by 16 highly competent observers. He says:—"The value of the service rendered by the examiners has in most cases been enhanced by its having extended over the whole five months during which the facts have been accumulated; so that increasing skill has been attained, and more uniformity of result has been secured. Your secretary becomes more and more convinced that a competent examiner is not made in a day, or even in a month; and that, even with large experience, much judgment and capacity are needful to interpret rightly the acts of the examined, whether educated or uneducated. This necessity is perhaps most strongly exhibited in the case of the partial colour-blinds of intelligence; who, although they may have a much feebler appreciation of the difference between red and green, for example, than the normal, may, after accurate observation and comparison, separate the red wools from the green. When tested, however, with coloured lights, their defects come out strikingly; and it becomes clear that they are totally unfit for responsible posts in which rapid appreciation of colour at a distance is required."

A remarkable instance of the difficulties which are sometimes placed in the way of the examiner, and of the care and skill and knowledge which he may be required to exercise, is furnished by a narrative contained in the last annual report of the Supervising Surgeon-General of the Marine Hospital Service of the United States. The narrative is too long for quotation, but I will endeavour to condense its most essential features. It is in the form of a report, by Surgeon Hutton, on the case of a colour-blind pilot at Detroit.

According to the rules issued last year by the United States Government, all persons applying

that attempts have been made in the United States to make political capital out of the question of colour-blindness, and that hence the authorities have been somewhat hampered in their efforts to deal with it on scientific and practical grounds alone, and have been led from time to time to modify, out of consideration for cases of real or supposed hardship, the rules under which their officers are instructed to act.

On the 21st of August, a prominent citizen and shipmaster of Detroit was sent to Surgeon Hutton for examination, and was reported by him to be completely colour-blind. The local and supervising inspectors called upon the surgeon to suggest that there must be a mistake, saying that the applicant had sailed vessels for 32 years, 24 of them under a pilot's license, that some, if not all, of the inspectors had sailed with him, and were certain that he could distinguish coloured lights as well as the best, and that he had never made a mistake or met with an accident. They wished to have a certificate of incompetence instead of one of complete colour-blindness, as the former would have referred back the matter to them, while the latter left them powerless. Mr. Hutton replied that the applicant was either completely colour-blind, or not colour-blind at all; but he accepted the invitation of the inspectors to see him informally tested with coloured lights. A room in the Custom-house was darkened, and a lantern was so arranged so as to show either a white, a red, or a green light, and was placed at 20 or 25 feet from the person examined. The light used was about six inches in diameter, but being transmitted through a bull's-eye appeared larger, say eight inches in diameter. Several times the examined pronounced the red to be green, the white to be green, and sometimes the green to be red. Splitting the light so as to show the port or left half as red, and the starboard or right half as green, precisely as they appear as to position on shipboard, he every time said both sides or halves were green, but of different

yellow-green. About an hour was occupied in the investigation, and the test sample in one hand, compared with it every other with dozens of skeins of each colour and rejected.

Four skeins each of good green then taken from the pile, misplaced apart. Asked how many replied, eight, of course. He said four were of a good green, and five were asked to separate them greens. In his best endeavours each, but more frequently all, greys, saying, as to the greens, reddish cast.

After a variety of other tests the same results, the applicant the streets and on the river, at night and by the inspectors, who steadily readily distinguish red and green stores and on vessels. They appealed to Hutton, saying that it was impossible him with coloured lights in the shipping in the harbour. They were so persistent that a practical trial was arranged. After an examination by gas light, in which the same was made as in the day, the party proceeded to the streets, and from here I take Mr. "Three or four blocks away, up a series of four red and six green lights in a triangular form over a saloon. These he properly described; a light on a car on Larned-street. Toward-avenue, two street cars a block side by side, one showing a green a bright light, were pointed out. The bright light was pronounced green light was pronounced red. were made to have him correct himself persistently adhered to his statement green light was red and the bright

ne, but no other. Three moving red lights properly named. Three of same in opposite were made out as two only. He 'saw' lights when none existed; also, in one instance, out a red light when none existed. On the shores of the Great Western Railroad he took both red and green lights, but it was able to separate them. Returning to Detroit, he made mistakes as to street-car lights. Along Woodward-avenue, we stopped at Frizell's drug store, in the windows of which were eight coloured globes, red, green, and blue.

In order that no mistakes, as to the lights were examined, might be made, the superintendent crossed over, and with his cane held them out one by one; of the eight coloured lights all brilliantly lighted, he properly named them; a green globe he said was red, and a red globe he said was green.

He then entered upon this last task with the intention that if the applicant made no mistake in the test, as some of the inspectors and assistants were so confident he would not do, I would give him the benefit of it so far as it lay in my power, and would proceed to criticise the thinness of the worsted tests. But, when he showed lights of which he knew nothing, it occurred to me that I decided within five minutes after giving the first examination, and showed a diagnosis of completely colour-blindness. So far as the test on the river vessels is concerned, I maintain that it is still a failure. Vessel lights have fixed positions. The use of mental calculation, coupled with his knowledge of the relative positions of these lights, enabled him to decide the matter, after a little time, as to the position and course of the vessel independently of his chromatic sense.

An amusing instance corroborative of my remarks occurred on the last morning. He walked into my office remarking, 'Doctor, you say I am colour-blind; you know I can see red; but you.' Walking up to the table on which were the worsted—and although, in order to give him the benefit of every doubt, I had purchased a dozen or so of samples of the brightest red, blue, and green, and put away all doubtless—he seized a skein, and approached me, saying, 'there is as good a red as God Almighty made.' However, it was the best of brown. It is clear that there can be no doubt that the applicant was in the wrong case, if it had not been for the testimony of Mr. Hutton in the discharge of his duties. He could have been referred to the inspectors for their examination, and would by them have been permitted to return to his avocation, on the ground of the insufficient test furnished by the results which he applied to the moving lights of the vessels.

Colour-blindness constitutes a real peril in navigation, and is curiously illustrated by the report for the current year of the railroad commissioners for the State of Connecticut, who have heardless frequently the question so common some time ago, "Who ever heard of an accident due to colour-blindness?" Many accidents which, in fact, of colour-blindness was less known, unaccountable, are now found to have all the characteristics which would be expected in

accidents from colour-blindness, and in some instances the proof is conclusive. The following is a remarkable instance of this.

A few years ago a collision occurred near Norfolk, Virginia, between the tugboat *Lumberman* and the steamship *Isaac Bell*, resulting in the loss of ten lives. A coroner's inquest was held without definite result, the general impression being that one or the other of the pilots was intoxicated. There was no proof of this, however, and the pilots were released. The pilot of the tugboat *Lumberman* was examined by the surgeon of the marine hospital service, during the current quarter, and found to be colour-blind. A rumour has reached the marine hospital bureau that the pilot of the *Isaac Bell* is also colour-blind.

Evidence, uncertain it is true, but of some weight, of accidents through colour-blindness may be found in the results of our Connecticut examinations. Dr. Carmalt says that he found no engineer over 31 years of age who was colour-blind, and the total average was only three per cent. in the State. Now, as it is agreed that about four per cent. is the average among men, and as our men examined were largely old *employés*, we may fairly assume that about one per cent. had been eliminated through mistakes, in fact caused by colour-blindness, but, as that was not thought of at the time, they were discharged for what was called carelessness.

In the face of the facts and arguments already stated, it becomes a serious question what precautions should be taken by the governing bodies of railways, if necessary under compulsion from the legislature, to secure the traffic of their respective lines against the risks which colour-blindness seems in the long run certain to entail. Considering the extent and character of these risks, and the inadequacy of any other defence against them, I think it is not too much to require that the colour-blind, for the future, should be absolutely excluded from railway or naval employment. The absolute number of persons affected by such a provision would, no doubt, be large; but the comparative number would be small; and there is no real hardship in excluding four per cent. of the male population from duties which they are not qualified to fulfil. The subject is one which might with great advantage be taken up by the amalgamated engineers and other trade societies, or, better still, by school boards, with a view to the early testing of the colour vision of children and of candidates for apprenticeship, and in order to exclude the colour-blind from occupations for which they are unfit, before they had spent time in preparing for them. Failing this, a strict examination should certainly be instituted by all railway companies, and no man should be permitted to enter their service, in any position in which colour-vision was or might be required from him, unless the results of the examination were entirely satisfactory.

It is strongly held by the majority of ophthalmic surgeons that every such examination should be conducted by trained experts; and in the United States, where this opinion has already found legislative expression, it is certain that passengers would not consider their safety adequately provided for, and that engine drivers and others would not submit to be condemned, by any verdict save that

...and then to say to candidates for employment, whose cases were reported as doubtful, that they must obtain certificates from the appointed expert before they could be considered eligible for employment. Whether the fee should be paid by the company or by the candidate would be a matter of arrangement between them.

The mode of examination which I would suggest, as falling within the capacity of the officers of the companies themselves, would be very simple. I would let them call upon each candidate rapidly to sort into two heaps twelve skeins of wool, six of which should be red and six green, both in gradations of colour, and to throw all the red into one heap and all the green into the other. Any normal sighted person would accomplish this sorting very quickly, and with absolute ease and certainty; and any candidate who did this should be considered as having passed in colour. Any candidate who rapidly made a wrong selection should be rejected without hesitation. Any candidate who sorted his wools slowly, and as a result of careful comparison, would at least have defective colour sense, and should be referred to experts to decide upon his exact condition. He would probably belong to the class of the incompletely colour-blind; whose condition is such that they can distinguish red from green in certain circumstances and at short distances, but not under all circumstances, nor at all distances. It would then be the duty of the expert to pronounce upon the degree of the defect, and it would be the duty of the railway authorities to decide whether that degree amounted to a disqualification in the course of the particular man; due regard being had to his capacities in other respects, or to his claims, from past service or other causes, upon the consideration of his employers.

The visibility of an object depends upon the size of the surface within the eye which is covered by its image; and this again upon the two elements of size and distance, which govern the dimensions

candidates for masters or ma  
there can be no doubt that  
this department of the Govern  
recognition of the requirem  
safety in this respect. Acco  
return, only 26 candidates

ions into which inquiry should be made, and conducted in the following manner. The ner is furnished with thirty cards, of which e white, five black, five blue, five red, five , and five yellow, the colours being all ted. Shuffling the cards, he withdraws me, now another, and, suddenly showing it candidate, asks what colour it is. Correct are accepted as evidence of correct colour- ; and the examination is carried further by of coloured glass, held up between the per- amined and a window. Now I think it quite ble that an intelligent man, trained, as the r-blind often are, to study slight dif- es of luminosity, might conceal colour-blind- throughout such an examination. Assuming o be red-blind or green-blind, and these are t common forms, he would be in no danger he rest of the cards, and the very saturated d greens would present to him marked dif- es of luminosity. I think that a case of in- e colour-blindness, which might entail anger from incapacity to recognise colour at sufficient distances, might entirely escape y. For naval purposes, the examination e confined, as in the railway services it , to red and green alone; on account of the e colours of signal flags; and I think it e rendered perfectly safe by the same h which I have suggested for railways, a odified to meet the altered circumstances. miner should, I think, have his tests in with five or six shades of each colour, and ndicate should be required to sort them y into heaps.

is not the practice of the Board of Trade to certificates to colour-blind applicants, but endorse the fact of colour-blindness upon tificate. In this way the officer himself, and, ployer, are alike warned of his defect, and, he may be engaged on account of his other ilities, neither he nor they will have any s for trusting to his power of discrimina- colour-signals. If the wool test were adopted service, I would suggest further that, as in e of railways, the subjects of incomplete r-blindness should be tested by experts with e to degree, and that this should be endorsed the certificate as well as the complete forms e affection. I trust, however, that the is not far distant when proper examinations g childhood will prevent persons from taking first step in callings for which they are festly unfit.

ave left myself very little time in which to e of the influence of colour-blindness upon e callings; and, in the few words which I can e to this part of the subject, I may mention it seems to be really an advantage to engravers, generally to all persons who produce illustra- in black and white, on account of the in- ed acuteness of perception of the variations ght and shade to which it appears to lead. ny other callings it presents a serious impedi- to success. There was a clerk in a Govern- office in London whose desk was furnished three bottles, containing respectively, red, blue, black ink; and he only knew which was which lacing them before him in some definite order. as the pleasure of mischievous boys in the

office, who had found out the clerk's defect, to change this order whenever his back was turned; and the result was that he used to bring to his superiors parti-coloured letters for signature. He was transferred to a department where it was his duty to tick off certain entries with black ink and others with red; and here he succeeded in producing a confusion which has hardly yet been disentangled, and which ultimately led to his dismissal. Dr. Joy Jeffries tells me of a portrait painter in New Boston, so skilful in his drawing that he gets £100 or £200 for a portrait, but who has to employ somebody else to mark his reds and greens before he ventures to use them. He also mentions three brothers who are colour-blind. One of them was a carriage painter, and he had to have his paint-pot given him by somebody else before he could begin to work. Another was in a furniture store, and could not rise above a packer, in consequence of having tried to persuade an old lady to buy a red sofa to match with green chairs. The third was in a large dry goods store, but could do only menial work in consequence of his defect. Dr. Jeffries also tells me of a medical student, who was plucked in his examination on account of errors in discriminating the actions of chemical tests, which were afterwards discovered to be due to colour-blindness; and in his book on the subject he mentions the case of a post-office clerk in Prussia, who was found to be constantly wrong with his accounts about the stamps. But at length it was discovered that he was colour-blind, and could not distinguish red from green stamps, so that he was perpetually in error about his charges for those which he issued to purchasers. A volume might be written about the possible mistakes of the colour-blind, but it would not materially advance our knowledge for any practical purpose. The most remarkable are those committed, when two colour-blind persons reinforce each other, as in the case of the gentleman who went to match some red wools for his wife, and succeeded, by the luminosity of sample, as long as only the bundle of red wool was brought to him to select from. At last a time came when a colour-blind shopman brought him a bundle of green wools, and from this the two together selected their matches for the red with entire complacency.

In a large number of civilised countries, the facts which I have roughly brought together in these lectures have already induced steps to be taken by persons in authority to provide against the dangers of the situation. In England, as I have stated, the Board of Trade was early in the field, and, thanks to the powers committed to it, is able to afford protection to the mercantile marine without a special act of parliament being required. In Norway and Sweden, where railways are more under control than with us, similar arrangements have been made with regard to them. In various continental countries people are becoming more and more attentive to the subject; but the lead has been taken in the United States. Massachusetts was the first to legislate; and a stringent law has quite recently been passed in Connecticut, which requires the whole *personnel* of the railways of the State to be examined for colour-vision every two years by a "competent person;" a phrase which, if it were used in England, would furnish much employment to the gentlemen of the long robe.

would compel all railway companies to have their servants tested for colour-vision by scientific methods; although it might fairly be left to the companies themselves to employ the colour-blind, if they chose to do so, in any capacity in which their defect was not a source of danger. But colour-blindness should at least be made known; and there should be no possibility of lives and property being sacrificed through ignorance of its existence.

## MISCELLANEOUS.

### CHINA GRASS DRESSING MACHINES.

By C. G. Warnford Lock.

I have just received from the Agricultural Department of the Indian Government a report on the trials of the China grass machines, which was intended for incorporation in the article on "Fibrous Substances" in Spens' "Encyclopædia." It has arrived too late for this purpose, but will probably interest readers of the *Journal*.

The seven competing processes may be thus briefly described:—

1. J. P. Vander Ploeg's appliances consisted of a crushing and a scutching machine; he cleaned the fibre finally by boiling it in a prepared liquor.
2. J. Nagoua used a combined crushing and scutching machine, adaptable to both operations.
3. R. H. Collyer boiled the stems first in water with a very little soda, then passed them through a machine which broke them up, and again through the same to clean them. He had also a smaller manual machine, costing only £60, but unsuitable for a regular factory.
4. Laberie and Berthet's machine crushed the stems, which were kept constantly wetted; the fibre was then steeped in a bleaching liquor and an alkaline liquor.
5. J. Cameron abandoned the machines described in his specification, and brought a hand implement.
6. C. W. Ames broke the stems in a machine

upon native methods current in India, and applied in many of the Indian grasses; it can be employed upon long stems, but would hardly be a success in a station where many acres had to be treated. Therefore the recommendations are to Nagoua and Vander Ploeg, and

The committee conclude that, if put upon the samples produced, it does not seem probable that they yet be able to compete with the plant can be grown in the moist parts of Burma, Upper Assam, northern Bengal, with only the promise for a rather superior crop, it is commercially. Until this has proved, and a real need has arisen of treatment, the Government renewing the offer of prizes; as with maintaining some acres of cultivation, for supplying roots to India.

Thus, even after much experience of the matter, and with every improvement in the machinery of Europe are complete inability to match the Chinese. It may be incidentally the seven competitors no less than their proposed plans, these four in fact seem to indicate an acquaintance with the material amounts to an acknowledgment that they had been working in this may probably help to account for the success. On the other hand, of the (the Frenchmen) have presumed experiment upon the plant which in the south of France, and the well known among Continental. The moral of this is the necessity on the part of English manufacturers.

### CINCHONA CULTIVATION

Surgeon-Major George King, the Royal Botanical Garden, Calcutta, reports that the Government of India have decided to purchase the land for the cultivation of cinchona in the hills of the Eastern Ghats.

bark trees and trees of the still unnamed hybrid. It has not been deemed necessary to increase number of *Succirubra* trees, from which the cinchona is manufactured. There are now more than millions of these trees on the two plantations of poo and Sittong, and this is considered quite sufficient to provide red bark for a much larger consumption of the febrifuge than there is any reason immediately to anticipate. Endeavours have therefore been directed to increasing the stock of quinine-producing to meet the demand for sulphate of quinine in the local and different departments of the Government. There are two descriptions of these trees on plantations, the supposed hybrid variety and the *ya*. Of the former, which yields a bark rich in quinine, 90,320 plants were put out during the year, 5,000 at Mungpoo, and 5,000 at Sittong, and the number now on the plantations is 199,898. Attention has been devoted to the propagation of the *Ledgeriana* variety of *Calisaya*, which is locally rich in quinine, and 99,415 trees were planted at Mungpoo. At Sittong 6,000 *Calisaya* trees were put out. There is a large nursery stock of *Ledgerianas*, the permanent plantation of this valuable variety probably will be largely increased during the current year.

The propagation of the species which yields the *agena* or Columbian bark has been retarded by the action of the "thrip" pest. This species was only introduced in January, 1880, when the late Mr. Bierbrought out four plants of it. There are now 60 plants and 90 partially rooted cuttings, and every year will be made to increase the stock.

The total number of trees of all kinds planted out in the two plantations of Mungpoo and Sittong is 720, this amount being made up of the following:—*C. succirubra* (red), 4,034,535; *C. calisaya* (w), 412,695; unnamed variety, 199,898; other, 50,592.

The produce of the plantations of the year was 15 lbs. of dry bark, against 361,690 lbs. in 1879-80, 51,659 lbs. in 1878-79.

A large number of trees of the interior kinds of *ya* were uprooted during the year. This species has several varieties, many of which, as Dr. King remarks, "produce barks which are essentially druggists' barks, being well suited for preparations, such as decoctions and tinctures, but being unsuited for the manufacture of febrifuge, and containing too little quinine worked profitably as sources of the pure sulphate of quinine." There being thus no way of disposing of a considerable quantity of yellow bark, a shipment was sent to London for sale. The opportunity was taken to send a small quantity of good *Ledgeriana* bark to get some idea of its commercial value. Dr. King remarks that yellow bark of any kind from the interior had never before been offered in the London market, and that, indeed, except at Mungpoo, it is not to be found anywhere in British India. The result was considered most satisfactory. *Ledgeriana* bark sold for 0d. per pound, and the inferior bark also fetched good prices.

The introduction of the Java plan of shaving the bark of living trees to the height of from 8 ft. to 10 ft. the ground was an interesting feature in the operations of the year. The results have been favourable under this plan the bark renews perfectly. Dr. King proposes to test by analysis whether the red bark is as rich in medicinal alkaloids as the yellow bark. But the Dutch plan of grafting *Ledgeriana* stocks, which was also tried during the year, was not attended with success. A further trial, however, will be made.

The general condition of the plantations is satisfactory. The growth of *Succirubra* in Sittong is not as flourishing as might be; but *Ledgeriana* and the hybrid variety are doing well. It is found that these two varieties do better on land with a southern exposure than on

land that looks to the north. It will thus be possible to utilise a considerable area which has hitherto been considered unsuitable for any kind of cinchona.

The total outturn of the febrifuge factory during the year was 9,296 lbs. The cost of manufacture, including the cost of the bark used, was Rs. 85,921 6s. 3p., and the average cost per pound rather less than last year. During the year 8,653 lbs. 13 oz. of febrifuge was disposed of as follows:—

	lbs.	oz.
To medical dépôt, Calcutta.....	3,000	0
" " Bombay.....	2,000	0
" " Madras.....	500	0
Sold to the public.....	3,150	11
Given as samples, &c.....	3	2

Total..... 8,653 13

The sales to the public are stated to be steadily increasing, and the febrifuge is said to be daily increasing in reputation as a thoroughly good cure for fever.

The financial results of the operations during the year were very satisfactory. The receipts from the sale of febrifuge and seed and plants, and the sale of bark in London, amounted to Rs. 1,79,657 2s. 11p.

The actual profit exhibited on the year's working was 80,290 rupees, equal to 8 per cent. on the capital of the plantation, while the value of the stock in hand at cost price was 94,294 rupees. This, however, does not represent the whole of the gain of the year. The price of quinine was very high, and the cost of 5,550 lbs., which would have been used by Government had the febrifuge not been available, would have been, at the lowest estimate, 5,50,000 rupees. The cost of the febrifuge used was only 90,880. There was thus a clear saving of 4½ lakhs of rupees. The savings effected by similar substitutions of febrifuge for quinine in previous years amounted to 11½ lakhs. The total saving therefore has already amounted to more than 16 lakhs of rupees.

The expenditure for the year amounted to Rs. 71,705 10s. 4p., being between one and two thousand rupees less than the budget estimate and allotment. In making out the accounts, care is taken to keep the expenditure of each plantation distinct. Dr. King observes that "the account of the Sittong plantation ought, when it is completed, to be of much interest to Cinchona planters, as they will show at how cheap a rate a plantation can be put out, when the price of experience does not form, as it so often does in new enterprises, a very heavy item in the capital expenditure."

#### ANTIMONY DEPOSITS IN SONORA.

In the recesses of a short range of mountains, the Sierra del Alamo Muerto, which skirts the eastern shore of the Gulf of California, at about thirty miles from the gulf, and fifty miles from El Altar, are several silver ledges, which have been worked from time immemorial by the Mexicans, and have recently passed into American hands. The most notable, says a writer in the *American Mail*, is the San Felix, which has been burrowed into to a depth of 700 feet on the incline. On the northern flank of the range an area of considerable extent is strewn with quartz and a heavy yellow mineral. This is said to have been long ago amalgamated for silver, but to have yielded so base an amalgam (perhaps from the presence of a little native antimony) as to have been rejected as a silver ore; and its true character seems to have been either overlooked or mistaken until recently. Samples were sent to England, where the value of the mineral as an ore of pure oxide of antimony was at once recognised. Shortly after that Professor Cox, late of the Indiana survey, made arrangements with the owners to ship the ore for treatment to works he had since erected in Oakland, Cal. There appear to be three systems of veins within an area of about 2000

permeates the mass of the ore, and seems to exist as chloride and iodide. The silver contents are said to be 125 dollars per ton, which is considered to be a very moderate estimate, as on the pile at the mouth of the Santa Margarita shaft it was difficult to find a lump whose joints were not more or less stained with silver, while many were thickly covered. Since then work has gone on actively on all three groups of lodes. On the first the ore bodies have been developed to a depth of 72 feet, on the second to a depth of 70 feet, and on the third to a depth of 118 feet, with no signs as yet of a change in the character of the ore or average size of the ore bodies, which, however, have never exhibited great uniformity in width. Two schooner loads have lately been shipped, and it is estimated that 5,000 tons of ore have been exposed by the superficial explorations recently made. A reference to Mr. Cox's papers on the native oxide of antimony, read before the American Association, will be found in this *Journal*, vol. xxviii., p. 874.

### NOTES ON BOOKS.

---

**Lathe-work.** By Paul N. Hasluek. London: Crosby Lockwood & Co., 1891.

There is no doubt that many interested in mechanics, especially as amateurs, have found the want of a good practical treatise on the amateur's tool *par excellence*, the lathe. "Holtzapfel" is too costly for everybody, and, besides, the original work stopped short before it reached the lathe. The introductory matter extended itself to such a length that the author had not time before his death to complete the work he had designed. Many other writers have tried to fill the gap, but, without casting any reflection on their efforts, it must be allowed that we are still without such a work as "Mechanical Manipulation" would have been had the elder Holtzapfel lived to finish his work. Of these writers, Mr. Hasluek is the latest, and his book will certainly bear comparison with those of any of his rivals. He seems to owe little to his predecessors, for his book looks like the result of original work and experience, and as such it will doubtless recommend

itself, entirely, wasted.

---

### GENERAL

---

**London Sanitary Protection & Arts' Room** on Tuesday, the 25th when Professor Huxley will preside. done during the last nine months, ab of Professor Fleeming Jenkin's pap Arts on January 12th last, will be giv members of the Society of Arts an meeting.

**Effects of Light on Vegetation** been making experiments lately on that the germination of certain agric meadow grass (*poa*) is much more fa heat. An experiment made with tr each, of *Poa nemoralis*, showed that cent. in light, and 8 per cent. in das were made with *Poa pratensis*, sho minating in light, and 7 per cent. i being a very variable force, experim with gas light, and with the same favours the germination of certain and that these germinate either not in darkness. The fact was verified whole series of seeds, such as *Festuca*, &c. In the case of seeds that germi such as clover, beans, or peas, Herr i is probably not advantageous.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,510. Vol. XXIX.

FRIDAY, OCTOBER 28, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## THE JOURNAL.

At the commencement of the new volume on October 18, certain alterations will be made in the paper used in the *Journal*, which it is hoped will improve its appearance. No change will be made in the size of the pages.

The regulations of the Post-office now permit papers to be stitched without incurring additional charge for postage, it is intended in future to use this in the *Journal*. This alteration, also, will coincide with the new volume.

## ARRANGEMENTS FOR THE SESSION.

The arrangements for the one hundred and seventh session of the Society have now been made by the Council, and full particulars will be stated in the next number of the *Journal*.

The first meeting will be held on the 16th of November, when the opening address will be delivered by Sir F. J. Bramwell, F.R.S., Chairman of the Council. Previous to Christmas, there will be ordinary meetings in addition to the opening meeting. Candidates proposed for election as members, are privileged to attend the opening meeting.

There will be four courses of Cantor Lectures during the session. The first course, on "Some Industrial uses of the Calcium Compounds," by Thomas Bolas, F.C.S., will be delivered before Christmas.

Two Juvenile Lectures at Christmas will be given by H. Preece, F.R.S., on "Recent Wonders of Electricity." Announcement of the arrangements for the Lectures will be made in due course.

## PATENT LAW.

An evening of Wednesday, November 30, will be devoted to a discussion on the Society of Arts' Bill, which will be continued on such other evenings as may be found convenient. The dis-

cussion will be opened by Sir FREDERICK BRAMWELL, F.R.S., Chairman of the Council.

The Secretary will be glad to furnish tickets for the meeting to persons interested in the subject of Patent Law who are not members of the Society.

## OWEN JONES PRIZES FOR FURNITURE DESIGNS.

The Council are Trustees of the sum of £400, presented to them by the Owen Jones Memorial Committee, being the balance of the subscriptions to that fund, upon trust to expend the interest thereof in prizes to "Students of the Schools of Art who in annual competition produce the best Designs for Household Furniture, Carpets, Wallpapers and Hangings, Damask, Chintzes, &c., regulated by the principles laid down by Owen Jones;" the prizes to "consist of a bound copy of Owen Jones's 'Principles of Design,' a Bronze Medal, and such sums of money as the fund admits of."

The prizes will be awarded on the results of the Annual Competition of the Science and Art Department. Competing designs must be marked "In competition for the Owen Jones Prizes."

The next award will be made in 1882, when six prizes are offered for competition, each prize to consist of a bound copy of Owen Jones's "Principles of Design," and the Society's Bronze Medal.

## PROCEEDINGS OF THE SOCIETY.

## EXHIBITION OF WORKS OF ART APPLIED TO FURNITURE, 1881.

The following Report of the judges appointed to recommend awards of silver and bronze medals, offered by the Society of Arts to the Designers and Art Workmen whose work was exhibited in the Exhibition of Works of Art applied to Furniture, held in 1881, at the Royal Albert-hall, has been received by the Council, and been approved by them.

1. The collection of works of Art included many branches of artistic handicraft, such as carving and inlaying in wood, ivory, &c., cabinet work and fine joinery, painting on various materials like wood, glass, and pottery, glass cutting, the process known as *pâte sur pâte*, beating and chasing metals like silver and brass, wrought-iron work, modelled and glazed stoneware, and decorative needlework. The arrangement of the objects had been undertaken by the various exhibiting firms. A definite space had been assigned to each firm, who decorated it with hangings or with painted and gilt moulded work, or wood panelling, &c., and then disposed within it the various objects of furniture, &c. We were much pleased with the general good

the medallions, merit the distinction of a Bronze Medal. In this Bay a tray and set of tea things, in a dark olive-green body, ornamented with applications of well-depicted forms in white paste (*pâte sur pâte*), exhibited by Messrs. Mintons, and designed and executed by Mons. Solon, we specially commend as worthy of a Silver Medal.

3. The decoration of the side of a room, exhibited by Messrs. Morant, Boyd, and Blanford, remarkable for the excellence and finish of the work, was based upon a scheme good in its proportions, and the blending of the delicate tones of colour adopted, with those of the damask panels, and the details of the ornamental forms used, redound to the good taste of the designer, Mr. V. Barnard. Messrs. Morant, Boyd, and Blanford also exhibit a satin wood cabinet, and we consider that Mr. H. Reich, who inlaid the frieze of interlacing garlands upon the front of the drawer and the central ornament of the flap should be rewarded with a Bronze Medal.

4. Near Bay No. 2 hung three red lustre plates, the work of Mr. W. de Morgan, to whom a Silver Medal should be given for suitability of design to the materials employed, as well as for the fine tones of colour and lustre obtained.

5. In Messrs. Jackson and Graham's cabinet and chimney-piece, of a so-called Oriental Greek character, extraordinarily delicate and perfectly fitting marquetry work, and very finished cabinet-makers' work, attracted attention. A Bronze Medal is due to Mr. A. Reich, the marquetry worker, and a Bronze Medal to Mr. A. Baldwin, cabinet-maker; to Mr. Marchant, who is understood to have assisted in the cabinet work, we award one of the Society's Certificates. Beneath the chimney-piece in rose-wood, with plaques of inlay of ivory, ebony, and mother-o'-pearl, designed by Mr. Allwright, was a wrought iron grate, of simple design, in good taste, made by Mr. Sayer, a member of the firm of Messrs. Festham and Co., who exhibited other grates and fire-irons of good pattern and workmanship. A piece of embroidery, designed by Mrs. Alfred

piece showed good cabinet-designer of these pieces is select for an award of a Bronze for his design for a white fittings. Some extraordinary cutting and engraving, by has produced a very remarkable "Portland vase," probably glass-cutting of modern times the "Milton vase," design of the Red-house Glass-works by Mr. Pargeter. To the Northwood, we award a Silver

9. Messrs. Wright and several excellent examples of English 18th century style Chippendale, Adam, and work, enamelled and decorated by Pergolesi. Awards of made to Mr. Thomas Hinton, and to Mr. Victor I worker, and of Certificates Bryne, Charles Humphreys cabinet-makers, by whom of these works were presented and gilt mirror frames and of the 18th century English French periods, especially sideboard, were noted for the carving being done by

10. The modelling of the by many hands, in a deep piece and cabinet exhibited and Lock, was particularly a Silver Medal to Mr. Webb and for many other special design for metal sconces was new in arrangement of composition, grouped, and modelled with relief and harmony in flow worker who wrought this (Singer, to whom we award

of design, with interlacements of rod and leaves of plate iron. The figures on panels, of deep modelled relief in terra-cotta and executed by Mr. G. Tinworth, expressive action, and we consider a Certificate should be awarded to this artist, award a second Certificate to Mr. Doulton, the designer of the large flattened bowl, executed in stoneware, and shown to Mr. Doulton; and a Certificate to Mr. Doulton, for his careful and clean painting on two tiles, called respectively "Companion" and "An Odd Chicken," to commend the skill displayed in two carved birds in lime-wood, the work of Mr. Doulton. Two panels of painted glass, suitable for decoration of a house or hall, representing "Science," appeared to us to show a appreciation of the application of coloured glass, without detracting from its utility as a medium through which light has to pass.

Bay No. 9, containing articles exhibited by Messrs. Gregory and Co., the reproduction of an English arm-chair, enriched with carved and painted rails, and a little tea-table, were highly commendable in workmanship, and commendable for the results of their construction. We award a Bronze Medal to Mr. W. P. Collins, the designer of these articles. To the designer, Mr. T. W. Hay, of the drawing, for the drawing and arrangement of the design, as well as for good harmony of colour, we award a Certificate.

The well-proportioned framework of walnut for the side of dining-room or hall, by Messrs. Johnstone, Jeanes and Co., in Bay No. 11, was excellent in design, but, in our opinion, the effect would have been better if simple panelling instead of tapestry had been used. As it produced the impression of an open space which had been filled up, rather than of a

The carving of the students of the School of Carving, South Kensington Museum, was vigorous; and the pilaster executed by Miss M. Rowe, of this school, showed good feeling for line and the modelling of surfaces. It is well to mention here that a principal object of this school is to cultivate the production of carving in a broad style, and at a cheap price similar to that used so largely for decorative purposes in the 18th century in this country. The objects of this school are not, therefore, intended to compete with more expensive and more highly detailed wood-carvings.

We award a Silver Medal to Mr. R. Gleeson, for suitable and graceful fan-mounts, which he designed and executed, especially that of mounted with Mechlin lace. The inlaid mahogany wood table, the work of Mr. Thomas, gained the distinction of a Bronze Medal, for the beauty of the marquetry work.

In concluding our report upon this Exhibition, we are of opinion that annual Exhibitions, at which our own various classes of Fine Art Applied to Industry, such as those represented at the present Exhibition, might be usefully supplemented by works for all sorts of handicrafts and manufactures to be encouraged to submit drawings and models of designs which have actually been carried out. A section was allotted for such draw-

ings at the Paris Exhibition of 1878; and, in our opinion, much useful instruction and information might be gained from such an annual display of designs to the benefit of producers and consumers.

GEORGE GODWIN (F.R.S.).

MONTAGUE GUEST (M.P.).

EDWARD J. POYNTER (R.A.).

ALAN S. COLE (Hon. Secretary).

5th August, 1881.

The Viscount Hardinge wrote to express his regret at being prevented from attending the meeting.

## LIST OF AWARDS.

### SILVER MEDALS.

Mons. Solon, for olive green tea service, *pâte sur pâte* (Messrs. Minton).

Mr. de Morgan, lustre plates.

Mr. Webb, modeller and designer (Messrs. Collinson and Lock).

Mr. R. Gleeson, for carved fan mounts.

Mr. Northwood, for glass cutting and engraving (Mr. Pargeter).

### BRONZE MEDALS.

Mr. H. Scholz, for painted furniture (Messrs. J. G. Grace and Son).

Mr. Vernon Barnard, designer of side of room (Messrs. Morant, Boyd, and Blanford).

Mr. J. B. Randal, furniture designs and design for fender (Messrs. Howard and Co.).

Mr. Albert Reich, marquetry worker (Messrs. Jackson and Graham).

Mr. H. Reich, marquetry worker of cabinet (Messrs. Morant, Boyd, and Blanford).

Mr. William Allwright, designer of rosewood chimney-piece, inlaid with ivory, ebony, mother-o'-pearl (Messrs. Jackson and Graham).

Mr. Baldwin, cabinet-maker (Messrs. Jackson and Graham).

Mr. T. Hinton, foreman cabinet-maker (Messrs. Wright and Mansfield).

Mr. Victor Reich, marquetry worker (Messrs. Wright and Mansfield).

Mr. Singer, for beaten brass-work (Messrs. Collinson and Lock).

Mr. G. Price, for beaten oxydised silver frame (Messrs. Collinson and Lock).

Mr. W. P. Collins, designs for furniture (Messrs. Gregory and Co.).

Mr. T. Jacob, for marquetry top to table.

### CERTIFICATES.

Mr. Marchant, cabinet maker (Messrs. Jackson and Graham).

Mr. C. Humphreys, cabinet-maker (Messrs. Wright and Mansfield).

Mr. T. Miller

Mr. S. Bryne

Mr. M. Anderson, carver (Messrs. Gillows).

Mr. T. W. Hay, designer of woven silken fabric for room decoration (Messrs. Gregory and Co.).

Mr. G. Tinworth, terra-cotta panels.

Mr. G. Tinworth, designer and modeller of flattened round bowl, shown by Messrs. Doulton.

Mr. Edward Sears, for painted tiles.

Miss Eleanor Rowe, for carved wood pilaster.

Mr. W. Perry, for carving in wood.

Mr. Sidney Phelps, wrought-iron work.

Mr. W. C. Godman, designer of panelling (Messrs. Johnstone and Jeanes).

## MEDALS OF THE SOCIETY OF ARTS.

The Society of Arts grew out of a suggestion made by William Shipley, a drawing master of Northampton, and brother of Jonathan Shipley, a well-known Bishop of St. Asaph. Shipley issued on June 8th, 1753, "Proposals for raising by subscription a fund to be distributed in premiums for the promoting of improvements in the Liberal Arts and Sciences, Manufactures, &c;" and in December of the same year he published "a scheme for putting the proposals into execution." The Society was formed in 1754, at a meeting held on 22nd of March at Rawthmell's coffee-house in Henrietta-street, Covent-garden. Premiums were at once offered for the discovery of cobalt and the growth of madder in this country, and for proficiency in drawing. With these offers the Society commenced its prosperous career. A proposal to give medals "on some occasions instead of money" was considered at the meeting of April 30th, 1755, but the matter was postponed as no action could be taken that year. Henry Baker, F.R.S., read a paper on March, 24th, 1756, proposing the distribution of medals as honorary premiums, in which he said—

"It is therefore proposed that a dye be made for striking medals of gold, silver, and copper (with proper devices), to be occasionally bestowed by the Society as a token of honour and esteem on such as shall practice or produce some new manufacture or discovery that may employ many hands, some considerable improvement of public utility, or some valuable branch of commerce in one or the other metal, according to the nature and consequence of the improvement or discovery; which medals in gold shall be of £5 value, and proportionately in silver and copper; though, in all of them, the honour of being thus distinguished is the principal object of regard."

This paper was referred to a committee for consideration on March 31st. The committee reported on April 7th that they were of opinion that the giving of medals would be of utility, and they suggested that a committee should be appointed to consider a proper device. Subsequently Mr. Baker submitted a sketch of a design, as did Nicholas Crisp and Mr. Ralph. Hogarth, Henry Cheere, and Nicholas Highmore were upon the medal committee, who agreed upon a device, and afterwards James Stuart, William Chambers, and Thomas Hollis, were added to the committee. After the design had been chased upon gold plates, and the order given for the dies to be cut, a difficulty arose. It was decided on March 23, 1757, that the value of the medal should not exceed ten guineas, but when specimens of the selected design were produced it was found that the die could not be carried out completely if less than 15 guineas' worth of gold was used. This was considered too much, and the report of the committee was referred back to them, with instructions to obtain a new device which should only need gold to the amount of five guineas. If, however, the device in hand could be executed for the proposed five guineas, this was to be preferred. On May, 24th, 1758, Mr. Yeo produced two gold medals, struck from the die which he had cast, the value of one being ten guineas, that of the other, £8 10s. This was not considered satisfactory, and the committee to whom the matter was referred declined to make

a report. The general meeting of the Society discussed the point on June 7, and resolved:

"That it is the opinion of this Society that a medal does not, both in execution and in value, answer the interest and expectation of the Society."

It was further resolved that dies and puns should be cut for a new medal, according to designs of Mr. Stuart, the value in gold not to exceed five, nor to exceed eight guineas, as to a former resolution. Mr. Stuart was not to appoint his own artist, and he chose Pingo, the famous die sinker, who agreed to make dies and punches for eighty guineas. It was quite satisfactory, but in November he found that he could not buy gold and silver at a licence, and Mr. Finchbeck (a rather different name, considering the metal associated with the name) was desired to furnish Mr. Pingo with gold and silver for the purpose. At last the Society obtained what they had so long been striving for, a thoroughly good medal, at a reasonable cost. On November 29, the thanks of the Society were unanimously given to Mr. Stuart, and a gold medal was ordered to be presented to him, for his care and trouble he had taken in this matter. On December 6, it was ordered:—

"That the inscription on the first gold medal is to be presented to Lord Viscount Folkestone, President of this Society, be forthwith engraved, as (in pursuance of the resolution of the 24th of May last):—On the reverse, without the wreath: To JACOB, VISCOUNT FOLKESTONE, PRESIDENT, within the wreath of olive, FOR EXCISEMENT SERVING."

Inscriptions for other gold medals were ordered at the same meeting. To Lord Romney, for his services; to Lady Augusta Greville, for her services; to the Duke of Beaufort, Philip C. Webb, F.R.S., and John Berney—all for their services, 1757; and to James Stuart, painter and architect, "for designing this medal." The reverse of the medal is shown in the annexed

First Medal of the Society.

There was much discussion in the Society respecting the inscription on the obverse of this medal. Thus in May, 1857, it was decided that the inscription should be "Arts and Commerce Promoted" instead of "Arts, Manufactures, and Commerce promoted." In November it was changed to "for Promoting Arts and Commerce," and the inscription as first proposed was adopted. The earlier draft the date of institution was

is, but afterwards it was fixed for the year

a medal was largely used for nearly half a century, but in 1801, James Barry took occasion in consequence of his additions to the pictures in the room, to suggest an improvement in the medal. He wrote:—

r. Barry begs leave to add, from a letter read by the Society, October 26th, 1801, that in consequence of the application for designs for a new die for medal, he stated his intention of introducing a variation of their former design, which he thought answer their intended purpose. The more the matter of that design is considered, the more we admire and respect the sterling good sense and judicious consideration of the original founders of the Society. Nothing can be more happily imagined than a medal consisting of Britannia aided by Minerva and Mercury, the classical tutelary deities of Arts, Manufactures, and Commerce; and this old device, like many good old usages, cannot be amended by any change of substratum. It requires nothing more in its execution, and will most happily coalesce and accommodate all the acquisitions and improvements of the most advanced and refined culture. For this purpose a little rest and character in the figures is all that is necessary, enlarging them so as to fill the space with dignity, and taking away from their individual appearance by the little graces and arts of a improved composition. And as there is always a noble dignity and consequence attached to magnificence, which is one of the constituents of sublimity, his suggested alterations would come to this—to substitute instead of the little entire figures of Minerva and Mercury, only two large heads of those deities, and he would omit the head of Britannia altogether, and by a bold and simple manner, rose, and thistle, totally rising the edge of the medal, playing in and out in a dignified manner, he would represent the present United Kingdom of Great Britain and Ireland, a felicity, at least, equal to the owl, the horse's head, or the dolphin on the Athenian, Punic, or Sicilian medals.

a full description of Barry's views is interesting, showing how completely they were carried out in the new medal. In 1802, a totally different medal was discussed. Application was made to Marchant, Associate of the Royal Academy, engraver, to prepare a die, and the Committee of Polite Arts recommended "The Society personified by a female, seated, having in her hand a wreath of laurel, and with the inscription directing attention to the statues of Minerva, Mercury, and Ceres, the ancient deities presiding over the Liberal arts—commerce and manufactures—the immediate objects of the Society." The reverse of the medal to be the head of the Society, with the date of his election, and the value of the gold to be twelve guineas. Mr. Marchant, into whose hands the work was placed, was to have been very dilatory, and after many delays it was decided, in April, 1805, to order him to suspend proceedings with the dies until he hears from the Society. The Committee of Polite Arts declared that it was expedient to resume the discussion as to the design at once; and they recommended the Society "That Messrs. Papworth, Marchant, Howard, Barry, and Trisham be severally applied to, professionally, to furnish rough sketches and designs for the intended medal."

\* Transactions—Vol. 19, pp. xxxvi—xxxix.

At a meeting of the Society, on the 4th December, 1805, a report of the Committee, recommending that Mr. Flaxman be desired to furnish a design, on the principle suggested by Mr. Barry, was read, when Barry made a motion to the effect that the report should be recommitted, but his motion was not agreed to. The next meeting, on the 11th of December, was apparently a stormy one, for a series of motions were brought forward, most of which were "disagreed to." At last, Mr. Wakefield made the definite proposition that "the name of Flaxman be erased, and that of Barry inserted;" but this did not find favour with the meeting, and eventually the original resolution of the committee was agreed to. Barry died in the following year, and then there was no obstacle to the completion of Flaxman's medal. Mr. Pidgeon prepared the dies, and in November, 1806, Flaxman expressed himself as highly pleased with the excellence of the execution. The Society were so

Medal designed by Flaxman.

pleased with the new medal, that they desired to have an engraving of it for publication in the Transactions. Flaxman proposed that his sister-in-law, Miss Denman, should make the drawing,

Another form of the Minerva medal.

and that the famous Anker Smith should engrave it. The engraving thus produced forms a frontispiece to the 25th volume of the Transactions. Among the medals presented in 1807 were these two:—

J. Flaxman, Esq., R.A., Buckingham-place, 1807

the design of the Society's new medal, modelled and presented by him—the first gold medal.

Miss Maria Denman, for her drawing of the new medal, the silver medal.

In 1818, it was found that the die for the Minerva medal was worn out, and Mr. Wyon offered to make a new one from Flaxman's original model, and to present it, in consideration of the liberal treatment he had always received from the Society. The thanks of the Society were voted to Wyon "for his very handsome offer" at the meeting on June 10th.

A case of fraud in the use of one of the medals came under the notice of the Society in the year 1813, which was summarily dealt with. The Minerva medal was given to an inventor "for his safe and economical fire of wood shavings," and the man engraved a representation of the medal on his business card, with the statement that the Society had presented it to him "for his invention of a superior method of preparing his materials for the manufacturing of pianofortes,

organs, and other musical instruments. Being called upon for an explanation, the painter tried unsuccessfully to excuse himself, and, on demand, he gave up the copper-plate cards. It was resolved by the Society should be destroyed, and all impressions burnt, with the exception of two to be kept in the minutes. At the meeting of May 26th

"The Society deeming it proper to have the tickets destroyed without loss of time, an order was given from the chair to that purpose, and it was burnt in the presence of the members."

#### HONORARY PALLET.

For a few years after the formation of the Society the only honorary reward was Stuart's medal. About the year 1766 it was thought expedient to adopt some honorary premium in place of rewards for such successful candidates in the different Sections (more particularly that of Polite Arts) who were under age. At a meeting of the

Obverse of Pallet.

Reverse of Pallet.

Committee of Polite Arts on January 28, 1766, it was resolved:—

"That these honorary premiums shall be pieces of wrought silver-plate, useful in, or allusive to, the particular art or branch of art in which the candidate claims (as drawing boxes, emblematical pallets, &c.), bearing an inscription exhibiting the name and age of the candidate, and the class and degree of premiums, &c., for which the same is given."

It was subsequently resolved that the pallet should be of an oval figure, 2½ inches by 2, of the thickness of half-a-crown. On March 21, two drawings which had been presented were considered, and one of them chosen. The die was to cost twenty guineas, and Mr. Johnson was desired to execute it.

There was a great silver pallet and a small one, and also in a few cases a gold pallet was awarded. The first award of the silver pallet was in 1767.

#### ISIS MEDAL.

The Society has always been greatly interested in the improvement of the art of die-sinking, and

at various times has offered premiums for that purpose. In 1809, Mr. T. Wyon, Jun., applied as a claimant for one of these, and produced

Isis Medal.

dies for a medal of Isis, which was highly approved, and in the list of awards for the year 1810 the following entry:—

Mr. T. Wyon, Jun., John-street, Blackfriars, made a medal die engraving of a beautiful head of Isis, patroness of the arts, the gold medal."

At a meeting of the Society on April 4th, 1811, it was resolved that this medal should be substituted for the greater silver pallet, as a reward in the department of Polite Arts. But at a subsequent meeting it was agreed that the change should be made at the option of the candidates, therefore we find in the lists of awards for that both pallets and Isis medals were given. Soon, the Isis medal became the favourite of the Society, and was largely given in the classes up to quite a late period.

#### CERES MEDAL.

In 1813, the Society's gold medal was given to William Wyon, of Birmingham, for a medal die engraving of the head of Ceres; and at the meeting

Ceres Medal.

In the 2nd of this same year, the advisability of using this medal for the purpose of award in the department of agriculture was considered. In gold and silver Ceres medals were awarded for improvements in agriculture.

#### VULCAN MEDAL.

In 1818, Mr. Mills produced a medal die of the head of Vulcan, which was approved by the Society,

Vulcan Medal.

It was agreed that it should be purchased, and used as a second medal for the department of mechanics, and the cost did not exceed twenty guineas, and was paid for the Isis medal. Gold and silver medals were given for the first time for improvements in mechanics in the year 1820.

#### SOCIETY'S MEDAL.

In 1849, the dies of the Minerva medal were found to be worn out, and it therefore became

necessary to take some steps for the preparation of a new one. Mr. (now Sir Henry) Cole suggested "That it would be desirable, if possible, to obtain permission to use the H.R.H. Prince Albert's medal dies for the Society, such dies being portraits of His Royal Highness, the Society's President." And he reported to the Council in April of that year that he had been informed by Colonel Phipps that His Royal Highness approved of the suggestion. In August, 1849, it was resolved by the Council—

"That instructions be given to Mr. Wyon to proceed forthwith in the preparation of the new larger die, with an impression of the head of H.R.H. Prince Albert, presented by His Royal Highness."

Society's Medal 1849-1861.

At the election of His Royal Highness the Prince of Wales to the Presidency, in 1863, his head was placed upon the obverse of the medal. At the same time the reverse was re-engraved; the wreath and inscription remained the same, but the engraving was bolder, and more artistic than that on the old medal.

#### ALBERT MEDAL.

The highest honour in the gift of the Society is the Albert medal, which was founded in memory of H.R.H. the Prince Consort, who was for eighteen years President of the Society. On the 4th February, 1863, the Council resolved:—

"That a gold medal, to be called the Albert medal, be provided by the Society, to be awarded by the Council not oftener than once a year, for distinguished merit in promoting Arts, Manufactures, or Commerce."

It was subsequently resolved that Mr. Leonard Wyon be requested to furnish the model for a head of the Prince at a late period of his life, the inscription to be "Albert, Prince Consort." It was decided that the reverse should be illustrative of Arts, Manufactures, and Commerce, and that several well-known artists should be invited to furnish designs. Ultimately, Mr. Leonard Wyon produced a design, which was accepted, and he then proceeded to prepare the dies. The first award of the Albert medal was in 1863, to Sir Rowland Hill: "For his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have extended over the civilized world."

Albert Medal.

Society's Medal from 1863 to the present time.

## MISCELLANEOUS.

### WHEAT CROP OF 1861.

The following calculations on this subject by Mr. J. B. Lawes, F.R.S., of Rothamsted are taken from the *Gardener's Chronicle*:—

"The seven seasons ending with 1861 have been more disastrous to British agriculture than any seven consecutive years of which we have a record. Those who hold the opinion that the fluctuations of the weather occur in definite cycles, will have some difficulty in finding a parallel to the period of the last seven years, without going back to very remote records. The change in the relative proportions of home-produced and imported wheat which has taken place during the last few years has entirely altered the character of the trade. In 1868-9, two-thirds of the total bread consumed was the produce of home-grown wheat. A few years later the requirements of the country were met by one-half of home-grown and one-half of foreign wheat. But the harvest of 1879 scarcely supplied one loaf in four required, that of 1880 only one in three, and that of 1881 will also supply only about one loaf in three required. We

cannot ignore the fact that, in consequence of great changes, the question of a good or bad crop, however important it may be to the landowner or the cultivator, is no longer of the same import to the nation at large as it was formerly. A point worthy of notice is that, although our requirements for foreign wheat are becoming larger and the fluctuations in the amounts required from year to year are becoming much less. Thus, after the season of 1860, the net imports of wheat increased from 4½ to 10 million quarters, or by more than 100 per cent. In 1872-3 the imports were 3,000,000 quarters more than in the previous year, corresponding to an increase of about 33 per cent. But after the harvest of 1879, the worst on record, when the net imports increased from 14½ to 16½ million quarters, the increase only amounted to about 16 per cent. In the year ending August 31, 1881, the amount of wheat retained for home consumption was more than sixteen million quarters. As the area under wheat in the United Kingdom was last year rather less than 3,000,000 acres, a deficiency of half a quarter per acre in the yield of the crop, although a very serious one so far as the interests of the cultivator are concerned, has comparatively little influence on the requirements of the country at large for foreign wheat. I have no doubt that my estimate of the home wheat crop of 1881

considerably too high. The average of the usually selected plots in my experimental wheat field showed produce of 27 bushels, reckoned at 61 lb. per bushel. There was at that time sufficient evidence to show how exceedingly bad was the yield of the crop upon the lighter soils; nor can I now account for the fact that in that year wheat grown continuously was so much better than wheat grown in rotation. For example: in the experimental field of light soil at Woburn the land growing wheat every year showed but little difference between the crops in 1879 and 1880; but where, in the same field, wheat was grown in an ordinary four-course rotation, after clover fed off by stock with cake or corn, without cake or corn, but an application of artificial manure, the produce of 1880 was from 11 to 16 bushels an acre less than under the same treatment in the very next season of 1879! In the following table is given produce in 1881, upon the same selected plots as usual, in the field at Rothamsted, which has now grown wheat for thirty-eight years in succession. There is also given for comparison the average produce on the same selected plots—over the last ten years, 1871-1880, over the preceding nineteen years, 1852-1870, and over the total period of twenty-nine years, 1852-1880, during which time the same manures have, in every case, been annually applied to the same plots:—

Harvests.	Unmanured. Plot 3.	Farmyard Manure. Plot 2.	Artificial Manures.			Means of Plots 7, 8, 9.	Means of Plots 1, 2 and 3, 4, 5.
	Plot 7	Plot 8.	Plot 9.

Average 29 years, 1852-80.....	58·0	60·0	59·4	59·1	58·6	59·0	59·0

TOTAL STRAW, CHAFF, &c., PER ACRE IN CWTs.							
1881.....	10½	31½	19½	20	32½	28	19½
Average 10 years, 1871-80.....	9½	29½	29½	37½	41½	36½	34½
Average 19 years, 1852-70.....	12½	35½	35½	41½	41½	39½	36½
Average 29 years, 1852-80.....	11½	33½	35½	40½	41½	38½	37½

These figures do not show much prospect of an abundant harvest. The yield per acre is low and the quality indifferent. In no case among the nearly forty plots in the experimental field does the weight per bushel reach 60 lb.; and the produce of straw is at the same time exceedingly low. In an adjoining field twenty-one varieties of wheat were grown side by side; not long before harvest the crops presented an exceedingly luxuriant appearance, and it was considered that the

yield would be from 50 to 62 bushels per acre. The result of the threshing is, however, disappointing. The highest produce in the field is only 54 bushels per acre, with a weight per bushel of 57½ lb.; and the lowest produce is, in two cases, 39½ bushels—in one with a weight of 61 lb., and in the other of scarcely 59 lb. per bushel. It is, I think, quite evident that the yield of the wheat crop will vary very much, not only in different districts, but in the same district, and that in different fields on the same farm. The produce in my experimental field, taking the mean of the same selected plots as for many years past, shows an average of 24 bushels per acre, reckoned at 61 lb. per bushel; and assuming an average crop of wheat to be 28 bushels the crop is 14 per cent. below the average.

According to the returns of the Registrar-General, the population of the United Kingdom was a little below 36,000,000 on June 30, 1881. Making due allowance for the natural increase, the mean population to be fed during the year commencing September, 1, 1881, and ending August 31, 1882, will be 36,280,000. Estimating the consumption at 5½ bushels of wheat per head, the quantity required to feed the population will be a little under 25,000,000 quarters. The area under wheat in the United Kingdom was, during the past harvest year, slightly under 3,000,000 acres. If the yield in my experimental field be taken as a guide, the total wheat crop of the country would not amount to 9,000,000 quarters; and deducting from this the amount required for seed, the quantity of home-produced wheat left available for consumption would be only about 8,000,000 quarters, and we should thus have to depend upon foreign supplies for nearly 17,000,000 quarters. As, however, wheat has risen considerably in price, and the potato crop is likely to be abundant, it is probable that our requirements for foreign wheat may be satisfied by an import equal to that which we have received during last the two years, namely, from 16,000,000 to 18,500,000 quarters. With a stationary or decreasing area under wheat, and a rapidly increasing population, it is probable that, before many years are past, the home produce of wheat will not furnish more than one-fourth of the total amount required.

#### OPIMUM IN CHINA.

In July, 1879, Mr. Robert Hart, Inspector-General of Customs at Peking, sent out a circular to the various Commissioners of Customs in China with a form of return, to be filled in with particulars on the following points:—1. How many catties (one catty = 1½ lb. avoirdupois) of boiled or prepared opium can be got from 100 catties of the drug in the crude or unprepared state. 2. Price of unprepared and prepared opium. 3. Weight of prepared opium smoked daily by (a) beginners, (b) average smokers, (c) heavy smokers. 4. How many pipes, one mace of prepared opium will fill. 5. Price of one mace of prepared opium at the retail shops or smoking rooms. 6. Total of unprepared opium of foreign origin imported at each port. 7. Total quantity of unprepared opium of native origin said to be produced. 8. Presumed length of time (months or years) a man must smoke before the habit takes such hold on him that he cannot give it up. 9. Sum total of charges and taxes to which 100 catties of opium are liable after paying import duty. On obtaining replies to these inquiries, Mr. Hart set himself to answer the question:—How many smokers does the foreign drug supply? with the following results which are taken from his report lately published at Shanghai.

The annual importation of foreign opium may be set down, in round numbers, as 100,000 chests (weighing 100 catties each) or 10,000,000 catties. The raw drug loses about 30 per cent. in weight when boiled down and converted into prepared opium, so that it is 7,000,000 catties only that reach the hands of the retail

opium, as already stated, is equal to about one pound and a third, a *voirdupois*. It is divided into 16 *liang*, and the *liang* is divided into tenths, called *mace*. The amount, therefore, of prepared opium for the supply of smokers is 120,000,000 *mace*. After paying import duties and *likin* taxes, the value of a *mace* of opium may be put at threepence half-penny. Average smokers consume three *mace* of prepared opium, and spend about 10*d.* daily. This quantity suffices for from 30 to 40 pipes, *i.e.*, whiffs, or "draws." Taking this calculation, Mr. Hart arrives at the fact that, in round numbers, there are about 1,000,000 smokers of foreign opium. Taking the population of China at 300,000,000, this will give the result, that  $3\frac{1}{3}$  in every 1,000 smoke, or, that the practice is indulged in by one-third of one per cent. of the population.

Besides the foreign drug, there is the native product, which is largely used. No trustworthy statistics could be obtained of the amount produced, and the estimates vary so greatly that they can only be set down as guesses. Mr. Hart, however, holds that, as far as is known at present, the sale of the native drug cannot exceed the foreign import in quantity. Putting it at the same amount, we arrive at the fact that there are two million smokers, or two-thirds of one per cent. of the population. The native product sells for one half of the price obtained for the foreign drug, and the total amount spent on the opium produced at home and imported from abroad is about £25,000,000 annually. Mr. Hart concludes his report with these words:—"Chinese who have studied the opium question are opposed to a traffic which more or less harms smokers, now numbering, say, over two millions, and annually increasing; at the same time, they admit that opium provides a large revenue, that the expenditure for opium, and liability to the incidence of opium taxation, touch an infinitesimally small per-centage of the population, and that neither the finances of the State, nor the wealth of its people, nor the growth of its population, can be specially damaged by a luxury which only draws from 5*d.* to 1*d.* a-piece a day from the pockets of those who indulge in it, and which is indulged in by only two-thirds of one per cent. of the population. They admit all this, but they do not find in either the revenue produced or the statistical demonstration of its per-centage innocuousness, any sufficient reason for welcoming the growth of the trade, or for desisting from the attempt to check the consumption of opium."

## CORRESPONDENCE.

### TANNING.

I am sure that we are upon the eve of a great change in the mode of tanning leather, and what is more to the point of this letter, *viz.*, the transportation of the raw material, hitherto looked upon as "dried bark" or "dried wood." In the latter case, it has at present to be carefully granulated, or else the tanning substances will not yield to the action of cold water. Extracts are now so much more understood, and thanks to the rising generation having studied in most schools and colleges the rudiments of chemistry, they understand the extraction of substances from raw products, and can watch any change that takes place; with a "Tannometer" or "Tan Tester" at hand, anyone with some evaporating pans could extract rich tanning materials in Australia, in India, or in South America, and get them into almost a solid form, so that they could be shipped home in barrels or casks.

The tanners in this country now find that they can work with these extracts much more expeditiously than they could with the old-fashioned process of bark.

Many of your readers having friends in our Colonies will render them a great service if they will call their attention to this fact, so that they may not allow the trade to fall into the hands of the Americans, which is now yielding them such enormous profits.

THOS. CHAMBER.

## GENERAL NOTES.

**Merchant Shipping.**—A chart, showing forty-four years' history of merchant shipping, has been issued as a supplement to the *British Trade Journal*. In this chart, the respective total tonnage of British, American, and French sailing vessels and steam-ships are given for each year since 1840, inclusive.

**London Sanitary Protection Association.**—The first general meeting of this association was held in the grounds of the Society of Arts, on Tuesday evening, 25th inst. Prof. Huxley, F.R.S., in the chair. Prof. Fleming-John, F.R.S., narrated the progress and success of similar associations in Newport, U.S.A., in Wolverhampton, in Bristol, and especially in Edinburgh, and announced that a association was just being formed in Brighton. The Chairman said that this association might be called a co-operative store for the supply of good advice on sanitary matters. The success of this association would be for the general good. Mr. Timothy Holmes, the hon. treasurer, said that the state of finance was satisfactory, for though the house was small, the expenditure was still smaller, leaving a satisfactory balance in hand.

**Patent Bill.**—At a meeting of the Cleveland "Iron Trade" Foremen's Association, held in Middlesbrough, Sunday, October 28th, 1881, a paper, by Sir Frederick J. Bramwell, C.B., on the Society of Arts' proposed Patent Bill, was read by the president, Mr. John M. Oubridge. In the discussion that ensued, an epitome of the Bill itself was read by Mr. Jeremiah Head (honorary member of the association). The following resolutions were carried unanimously:—Proposed by Mr. Jeremiah Head, and seconded by Mr. J. M. Oubridge, and supported by several other gentlemen; 1st. "That the Cleveland 'Iron Trade' Foremen's Association heartily approves of the Society of Arts' proposed new Patent Bill, and pledges itself to support it by every available means." 2nd. It was proposed by Mr. J. M. Oubridge, and seconded by Mr. Robert Telford, "That Mr. Jeremiah Head be authorized and requested to communicate with Sir Frederick J. Bramwell, in order to obtain his advice as to the best means of carrying out the first resolution."

**School Board Drill.**—The annual drill competition of the London Board schools, for the challenge banner presented by the Society of Arts, took place on Saturday, 26th October, in the grounds of Lambeth Palace. About 80 boys from the following seventeen different Board schools took part in the contest:—First column—1. Marlborough-street, St. Pancras; 2. Thomas-street, Limehouse; 3. Plumstead-road; 4. Tennyson-road, Battersea; 5. Portman-place, Mile-end; 6. Fearouse-street, Walworth; 7. Larkhall-lane, Clapham; 8. "D" Street, Queen's-park; 9. Brompton-park-road. Second column—1. London-fields, Haringey; 2. Harper-street, New Kent-road; 3. Bellenden-street, Peckham; 4. Sumner-road, Peckham; 5. Watney-street, Hammer-smith; 6. Fairfield-road, Bow; 7. Harwood-street, Fulham; 8. Westmoreland-road, Walworth. Each school was represented by forty boys and an instructor. The contest took place before the judges, Mr. Freeman (the Chairman of the Board), Colonel Page, and Mr. Mr. Macgregor (Rob Roy), and the companies drilled equally in different parts of the grounds. After a variety of evolutions, the Marlborough-street School (St. Pancras) and the Portman-place school (Mile-end) companies were called to the front, and put to a final test to decide the winner when the choice fell on the Mile-end boys. The medals in order of merit were Marlborough-street (St. Pancras), Thomas-street (Limehouse), the last winners of the competition, of the Tennyson-road School, Battersea.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,511. Vol. XXIX.

FRIDAY, NOVEMBER 4, 1881.

*Communications for the Society should be addressed to the Secretary  
John Street, Adelphi, London, W.C.*

## NOTICES.

## ELECTRIC LIGHTING IN THEATRES.

R. D'Oyly Carte, the proprietor of the Savoy Theatre, in the Strand, has kindly made arrangements for Members of the Society, who may wish so, to inspect the lighting arrangements of Savoy Theatre, on the afternoon of Saturday, 4th of November, at ten minutes before five. Members will be admitted on presentation of their cards. Each member may be accompanied by a friend.

## ARRANGEMENTS FOR THE SESSION.

The first meeting of the One Hundred and twenty-eighth Session of the Society will be held on Wednesday, the 16th inst., when the Opening Address will be delivered by Sir FREDERICK J. BRAMWELL, F.R.S., Chairman of the Council. Up to Christmas, there will be four ordinary meetings in addition to the opening meeting. Candidates proposed for election as members are invited to attend the opening meeting.

## ORDINARY MEETINGS.

The following arrangements for the Wednesday meetings before Christmas have been made:—

EMBER 16.—Opening Meeting of the Session. Address by Sir FREDERICK J. BRAMWELL, F.R.S., Chairman of the Council.

EMBER 23.—“The Storage of Electricity.” By SYLVANUS THOMPSON, D.Sc.

EMBER 30.—Discussion on the Society of Arts' Bill, which will be continued on such other days as may be found convenient. The discussion will be opened by Sir FREDERICK J. BRAMWELL, F.R.S., Chairman of the Council.

EMBER 7.—“The American System of Heating by Steam.” By Capt. DOUGLAS GALTON, C.B.

EMBER 14.—“Electric Lighting at the Paris Universal Exhibition.” By W. H. PREECE, F.R.S.

## FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place

on the following Tuesday Evenings, at Eight o'clock:—

January 31; February 28; March 21; April 4, 25; May 23.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

The meetings of this Section will take place on the following Thursday Evenings, at Eight o'clock:—

January 26; February 23; March 9, 30; April 27; May 11.

## INDIAN SECTION.

The meetings of this Section will take place on the following Friday Evenings, at Eight o'clock:—

February 17; March 17, 31; April 21; May 12, 26.

## CANTOR LECTURES.

The First Course will be on “Some of the Industrial Uses of the Calcium Compounds.” By THOMAS BOLAN, F.C.S.

November 21, 28; December 5, 12.

The Second Course will be on “Recent Advances in Photography.” By CAPT. ARNEY, R.E., F.R.S.

January 30; February 6, 13, 20.

The Third Course will be on “Hydraulic Machinery.” By PROF. JOHN PERRY.

March 6, 13, 20, 27.

The Fourth Course will be on “Book Illustration, Old and New.” By J. COMYNS CARR.

April 20; May 1, 8, 15.

## JUVENILE LECTURES.

The two Juvenile Lectures will be by W. H. PREECE, F.R.S., on “Recent Wonders of Electricity.” The dates for these are Wednesday evenings, December 28 and January 4. A full programme of the Sessional Arrangements will be given in next week's *Journal*.

## SOCIETY OF SCIENCE, LETTERS, AND ART.

It having come to the knowledge of the Secretary that circulars, purporting to be issued by “The Society of Science, Letters, and Art, of London,” or some similar title, and dated from Finsbury-park or Upper Tollington-park, have been sent to certain Members of the Society of Arts, inviting them to subscribe to the “Society of Science, Letters, and Art,” and that several subscriptions have been paid to the secretary of the above institution, under the impression that it was connected with the Society of Arts, he is desired to give notice that nothing whatever is known of such a society at this office, and that it is not associated in any way with the Society of Arts.

# **SOME OF THE DEVELOPMENTS OF MECHANICAL ENGINEERING DURING THE LAST HALF-CENTURY.\***

By Sir Frederick Bramwell, V.P. Inst. C.E., F.R.S.

Chairman of the Council of the Society of Arts.

I am quite sure the Section will agree with me in thinking, it was very fortunate for us, and for science generally, that our President refrained from occupying the time of the Section by a retrospect, and devoted himself, in that lucid and clear address with which he favoured us, to the consideration of certain scientific matters connected with engineering, and to the foreshadowing of the directions in which he believes it possible that further improvements may be sought for. But I think it is desirable that some one should give to this Section a record, even although it must be but a brief and an imperfect one, of certain of the improvements that have been made, and of some of the progress that has taken place, during the last fifty years, in the practical application of mechanical science, with which science and its applications our Section is particularly connected. I regret to say that, like most of the gentlemen who sat on this platform yesterday, who, I think, were, without exception, past presidents of the Section, I am old enough to give this record from personal experience. Fifty years ago, I had not the honour of being a member, nor should I, it is true, have been eligible for membership of the Association; but I was at that time vigorously making models of steam-engines, to the great annoyance of the household in which I lived, and was looking forward to the day when I should be old enough to be apprenticed to an engineer. Without further preface, I will briefly allude to some of the principal developments of a few of the branches of engineering. I am well aware that many branches will be left unnoticed; but I trust that the omissions I may make will be remedied by those present who may speak upon the subject after me.

I will begin by alluding to the *Steam-engine employed for manufacturing purposes*. In 1831, the steam-engine for these purposes was commonly the condensing beam engine, and was supplied with steam from boilers, known, from their shape, as wagon boilers; this shape appears to have been chosen rather for the convenience of the sweeps, who periodically went through the flues to remove the soot consequent on the imperfect combustion, than for the purpose of withstanding any internal pressure of steam. The necessary consequence was, that the manufacturing engines of those days were compelled to work with steam of from only  $3\frac{1}{2}$  lbs. to 5 lbs. per square inch of pressure above atmosphere. The piston speed rarely exceeded 250 feet per minute, and as a result of the feeble pressure, and of the low rate of speed, very large cylinders indeed were needed relatively to the power obtained. The consumption of fuel was heavy, being commonly from 7 lbs. to 10 lbs. per gross indicated horse-power per hour. The governing of the engine was done by pendulum governors, revolving slowly, and not calculated to exert any greater effort than that

of raising the balls at the end of the pendulum arms, thus being, as will be readily seen, very inefficient regulators. The connection of the parts of the engine between themselves was derived from the foundation upon which the engine was supported. Incident to the low piston speed, was slowness of revolution, rendering necessary heavy fly-wheels, to obtain even an approach to practical uniformity of rotation, and frequently rendering necessary also heavy trains of toothed gearing, to bring up the speed from that of the revolutions of the engine to that of the machinery it was intended to drive.

In 1881, the boilers are almost invariably cylindrical, and are very commonly internally fired, either by one flue or by two; we owe it to the late Sir William Fairbairn, President of the British Association in 1861, that the danger, which at one time existed, of the collapse of these fire flues, has been entirely removed by his application of circumferential bands. These days there are, as we know, modifications of Sir William Fairbairn's bands, but by means of his bands, or by modifications thereof, all internally fired boilers are so strengthened, that the risk of a collapse of the flue is at an end. Boilers of this kind are well calculated to furnish—and commonly do furnish—steam of from 40 lb. to 80 lb. pressure above atmosphere. The piston speed is now very generally 400 feet or more, so that, notwithstanding that there is usually a liberal expansion, the mean pressure upon the piston is increased, and this, coupled with its increased speed, enables much more power to be obtained from a given size of cylinder than was formerly obtainable. The revolutions of the engine now are as many as from 60 to 200 per minute, and thus, with far lighter fly-wheels, uniformity of rotation is much more nearly attained. Moreover, all the parts of the engine are self-contained; they no longer depend upon the foundation, and in many cases the condensing is effected either by surface condenser, or, where there is not sufficient water, the condensation is, in a few instances, effected by the evaporative condenser—a condenser which, I am sorry to say, is not generally known, and is therefore seldom used, although its existence has been well as long as that of the Association. Notwithstanding the length of time during which the evaporative condenser has been known to some engineers, it is a common thing to hear persons say, when asked them if they are using a condensing engine, "I do not use it; I have not water enough." A very sufficient answer indeed, if an injection condenser, or an ordinary surface condenser, constituted the sole means by which a vacuum condition might be obtained; but a very insufficient answer, being regard to the existence of the evaporative condenser, as by its means, whenever there is water enough to the feed of a non-condensing engine, there is enough to condense, and to produce a good vacuum. An evaporative condenser simply consists of a series of pipes, in which the steam to be condensed, and over which the water is allowed to fall in a continuous rain. By this arrangement there is evaporated from the outside of the condenser a weight of water which goes away in a cloud of vapour, of nearly equal to that which is condensed, and is returned as feed into the boiler. The same water is pumped up and used outside the condenser, and

\* Paper read in Section G. (Mechanical) of the British Association.

over, needing no more to supply the waste than would be needed as feed water. Although this condenser has, as I have said, been in use for thirty or forty years, one still sees engines working without condensation at all, or with water-works water, purchased at a great cost, and to the detriment of other consumers, who want it for ordinary domestic purposes; or one sees large condensing ponds made, in which the injection water is stored, to be used over and over again, and frequently (especially towards the end of the week) in so tepid a state as to be unfit for its purpose. The governing is now done by means of quick-running governors, which have power enough in them to raise not merely the weight of the pendulum ball, which is now small, but a very heavy weight, and in this way the governing is extremely effective. I propose to say no more, looking at the magnitude of the whole of my subject, upon the engine used for manufacturing purposes, but rather to turn at once to those employed for other objects.

*Steam navigation.*—In 1831, there were a considerable number of paddle steamers running along some of the rivers in England, and across the Channel to the Continent. But there were no ocean steamers, properly so-called, and there were no steamers used for warlike purposes. As in the case of the waggon boilers, the boilers of the paddle steamers of 1831 were most unsuited for resisting pressure. They were mere tanks, and there was as much pressure when there was no steam in the boiler from the weight of the water on the bottom, as there was at the top of the boiler from the steam pressure when the steam was up. Under these circumstances again, from  $3\frac{1}{2}$  lbs. to 5 lbs. was all the pressure the boilers were competent to bear, and as the engines ran at a slow speed, they developed but a small amount of horse-power in relation to their size. Moreover, as in the land engine, the connection between the parts of the marine engine was such as to be incompetent to stand the strain that would come upon it if a higher pressure, with a considerable expansion, were used, and thus the consumption of coal was very heavy; and we know, that having regard to the then consumption, it was said on high authority, it would be impossible for a steamboat to traverse the Atlantic, as it could not carry fuel enough to take it across; and indeed it was not until 1838 that the *Sirius* and the *Great Western* did make the passage. The passage had been made before, but it was not until 1838 that the passenger service can be said to have commenced. In 1831, the marine boiler was supplied with salt water, the hulls were invariably of wood, and the speed was probably from eight to nine knots an hour. In 1881, the vessels are as invariably either of iron or of steel, and I believe it will not be very long before the iron disappears, giving place entirely to the last-mentioned metal. With respect to the term "steel," I am ready to agree that it is impossible to say where, chemically speaking, iron ends and steel begins. But (leaving out malleable cast iron) I apply this term "steel" to any malleable ductile metal of which iron forms the principal element, and which has been in fusion, and I do so in contra-distinction to the metal which may be similar chemically, but which has been prepared by the puddling process. Applying the term steel in that sense, I believe, as I have said, it will not

be very long before plate-iron produced by the puddling process will cease to be used for the purpose of building vessels. With respect to marine engines, they are now supplied with steam from multiple-tubed boilers, the shells of which are commonly cylindrical. They are of enormous strength, and made with every possible care, and carry from 80 lbs. to 100 lbs. pressure on the square inch. It has been found, on the whole, more convenient to expand the steam in two or more cylinders, rather than in one. I quite agree that, as a mere matter of engineering science, there is no reason why the expansion should not take place in a single cylinder, unless it be that a single cylinder is cooled down to an extent which cannot be overcome by jacketing, and which, therefore, destroy, a portion of the steam on its entering into the cylinder. As regards the propeller, as we know, except in certain cases, the paddle-wheel has practically disappeared, and the screw propeller is all but universally employed. The substitution of the screw propeller for the paddle enables the engine to work at a much higher number of revolutions per minute, and thus a very great piston speed, some 600 ft. to 800 ft. per minute is attained; and this, coupled with the fairly high mean pressure which prevails, enables a large power to be got from a comparatively small-sized engine. Speeds of 15 knots an hour are now in many cases maintained, and on trial trips are not uncommonly exceeded. Steam vessels are now the accepted vessel of war. We have them in an armoured state, and in an unarmoured state, but when unarmoured rendered so formidable, by the command which their speed gives them of choosing their distance, as to make them, when furnished with powerful guns, dangerous opponents even to the best armoured vessels. We have also now marine engines, governed by governors of such extreme sensitiveness, as to give them the semblance of being endowed with the spirit of prophecy, as they appear rather to be regulating the engine for that which is about to take place than for that which is taking place. This may sound a somewhat extravagant statement, but it is so nearly the truth, that I have hardly gone outside of it in using the words I have employed. For a marine governor to be of any use, it must not wait till the stern of the vessel is out of the water before it acts to check the engine and reduce the speed. Nothing but the most sensitive and, indeed, anticipatory action of the governors can efficiently control marine propulsion. Instances are on record of vessels having engines without marine governors being detained by stress of weather at the mouth of the Thames, while vessels having such governors, of good design, have gone to Newcastle, have come back, and have found the other vessels still waiting for more favourable weather. With respect to condensation in marine engines, it is almost invariably effected by surface condensers, and thus it is that the boilers, instead of being fed with salt water as they used to be, involving continuous blowing off, and frequently the salting up, of the boiler, are now fed with distilled water. It should be noticed, however, that in some instances, owing to the absence of a thin protecting scale upon the tubes and plates, very considerable corrosion has taken place with distilled water, derived from condensers during

tinued brass tubes, has been used, and where the water has carried into the boiler fatty acids, arising from the decomposition of the grease used in the engine; but means are now employed by which these effects are counteracted.

I wish, before quitting this section of my subject, to call your attention to two very interesting, but very different, kinds of marine engines. One is the high-speed torpedo vessel, or steam launch, of which Messrs. Thornycroft's firm have furnished so many examples. In these, owing to the rate at which the piston runs to the initial pressure of 120 lbs., and to very great skill in the design, Messrs. Thornycroft have succeeded in obtaining a gross indicated horse-power for as small a weight as half a cwt., including the boiler, the water in the boiler, the engine, the propeller shaft, and the propeller itself.

To obtain the needed steam from the small and light boiler, recourse has to be made to the aid of a fan blast driven into the stoke-hole. From the use of a blast in this way advantages accrue. One is, as already stated, that from a small boiler a large amount of steam is produced. Another is that the stoke-hole is kept cool; and the third is that artificial blasts thus applied are unaccompanied by the dangers which arise, when under ordinary circumstances the blast is supplied only to the ash-pit itself. The second marine engine to which I wish to call your attention, is one that has been made with a view to great economy. The principles followed in its construction are among those suggested by the President (Sir W. G. Armstrong) in his address. He (you will remember) pointed out that the direction in which economy in the steam-engine was to be looked for was that of increasing the initial pressure; although at the same time he said that there were drawbacks in the shape of greater loss, by radiation, and by the higher temperature at which the products of combustion would escape. We must admit the fact of the latter source of loss, when using very high steam, it being inevitable that the temperature of the products of combustion escaping from a boiler under these conditions must be higher than those which need be allowed to escape when lower steam is employed; although I regret to say that in practice in marine boilers working at comparatively low pressures the products are ordinarily suffered to pass into the funnel at above the temperature of melted lead. But with respect to the loss by radiation in the particular engine I am about to mention—that of Perkins—there is not as much loss as that which prevails in the ordinary marine boilers, because the Perkins boiler is completely enclosed, with the result that while there is within the case a boiler containing steam of 400 lbs. on the square inch, and the fire to generate that steam, the hand may be applied to the casing itself, which contains the whole of the boiler, without receiving any unpleasant sensation of warmth. By Mr. Perkins's arrangement, using steam of 400 lbs. in the boiler, it was found, as the result of very severe trials, conducted by Mr. Rich, of Messrs. Easton and Anderson's firm, and myself—trials which lasted for twelve hours—that the total consumption of fuel, including that for getting up steam from cold water, was just under 1·8, actually 1·79 lb. per gross indicated horse-power per hour. That gross indicated horse-power was obtained in

a manner which it is desirable should always be employed in steamboat trials. It was not got by using as a divisor the horse-power of the most favourable diagram obtained during the day; but it was got from diagrams taken during the regular work; then, every half-hour, when the pressure began to die down from coal being no longer put upon the fire, diagrams taken every quarter-of-an-hour, and then, towards the last, every five minutes; and the total number of foot-pounds were calculated from these diagrams, and were used to obtain the gross indicated horse-power.

Further, so far as could be ascertained by the process of commencing a trial with a known fire, and closing that trial at the end of six hours, with the fire as nearly as possible in the same condition, the consumption was 1·66 lbs. of coal per gross indicated horse-power per hour. So that, without taking into account the coal consumed in raising steam from cold water, the engine worked for 1½ lbs. of coal per horse per hour. I think it well to give these details, because undoubtedly it is an extremely economical result. Our President alluded to the employment of ether as a means of utilising the heat which escaped into the condenser, and gave some account of what was done by Mons. Du Tremblay in this direction. It so happened that I had occasion to investigate the matter at the time of Du Tremblay's experiments: very little was effected here in England, one difficulty being the Excise interference with the manufacture of ether. Chloroform was used here, and it was also suggested to employ bi-sulphide of carbon. In France, however, a great deal was done. Four large vessels were fitted with the ether engines, and I went over to Marseilles to see them at work. I took diagrams from these engines, and there is no doubt that, by this system, the exhaust steam from the steam cylinder, which was condensed by the application of ether to the surface of the steam condenser (producing a respectable vacuum of about 22 inches), gave an ether pressure of 15 lbs. on the square inch above atmosphere, and very economical results as regards fuel were obtained. The scheme was, however, abandoned from practical difficulties. It need hardly be said that ether vapour is very difficult to deal with, and although ether is light, the vapour is extremely heavy, and if there is any leakage, it goes down into the bilges by gravitation, and being mixed with air, unless care is taken to prevent access to the fire, there would be a constant risk of a violent explosion. In fact, it was necessary to treat the engine-room in the way in which a fiery colliery would be treated. The lighting, for instance, was by lamps external to the engine-room, and shining through thick plate-glass. The hand lamps were Davy's. The ether engine was a bold experiment in applied science, and one that entitles Du Tremblay's name to be preserved, and to be mentioned as it was by our President. There was another kind of marine engine, that I think should not be passed over without notice; I allude to Howard's quick-steaming engine. The experiments with this engine persevered in for some considerable time, and it was actually used for practical purposes in a

alling a passenger steam-vessel called the *Vesta*, and running between London to Ramsgate. In that engine the boiler had a double-bottom, containing an amalgam of quicksilver and lead. This amalgam served as a reservoir of heat, which it took up from the fire below the double-bottom, and gave it out at intervals to the water above it. There was no water in the boiler, in the ordinary sense of the term, but when steam was wanted to start the engine, a small quantity of water was injected by means of a hand-pump, and after the engine was started, there was pumped by it into the boiler, at each half revolution, as much water as would make the steam needed. This water was flashed on the top surface of the reservoir in which the amalgam was confined, and was entirely turned into steam, the object of the engineers in charge being to send in so much water as would just generate the steam, but so as not to leave any water in the boiler. The engines of the *Vesta* were made by Mr. Penn, for Mr. Howard, of the King and Queen Ironworks, Rotherhithe. Mr. Howard, was, I fear, a considerable loser by his meritorious efforts to improve the steam-engine.

There was used, with this engine, an almost unknown mode of obtaining fresh water for the boiler. Fresh water, it will be seen, was a necessity in this mode of evaporation. The presence of salt, or of any other impurity, when the role of the water was flashed into steam, must have caused a deposit on the top of the amalgam chamber at each operation. Fresh water, therefore, was needed; the problem arose how to get it; and that problem was solved, not by the use of surface condensation, but by the employment of re-injection, that is to say, the water delivered from the hot-well was passed to pipes external to the vessel; after traversing them, it came back into the injection tank sufficiently cooled to be used again. The boilers were worked by coke fires, urged by a fan blast in their chimneys, but I am not aware that this mode of firing was a needful part of the system.

I come now to the *Engines used for railways*. At the British Association meeting of 1831, the Manchester and Liverpool Railway had been opened only about a year. The Stockton and Darlington railway line, it is true, had carried passengers by steam-power as early as 1825, but I think we may look upon the Manchester and Liverpool as being the beginning of the passenger and mercantile railway system of the present day. At that time the locomotives weighed from eight to ten tons, and the speed was about 20 miles per hour, with a pressure of 40 to 50 lbs. The rails were light; they were jointed in the chairs, which were generally carried on stone blocks, thus affording most excellent anvils for the battering to pieces of the ends of the rails—that is to say, for the destruction of the very parts where they were most vulnerable. The engines were not competent to draw heavy trains, and it was a common practice to have at the foot of an incline a shed containing a “bank-engine,” which ran out after the trains as they passed, and pushed them up to the top of the hill. Injectors were then unknown, and donkey-pumps were unknown, and therefore, when it was necessary to fill up the boiler, if it had not been properly pumped up before the locomotive came to rest, it

had to run about the line in order to work its feed-pumps. To get over this difficulty, it was occasionally the practice to insert into a line of rails, in a siding, a pair of wheels, with their tops level with that of the rails so that the engine wheels could run upon the rims. Then, the locomotive being fixed to prevent it from moving of the pair of wheels thus endways, it was put into revolution, its driving wheels bearing, as already stated, upon the rims of the pair of wheels in the rails, and thus the engine worked its feed pumps without interfering (by its needless running up and down the line) with the traffic. It should have been stated that at this time there was no link motion, no practical expansion of the steam, and that even the reversal of the engine had to be effected by working the slides by hand gear, in the manner in use in marine engines. When the British Association originated, although the Manchester and Liverpool Railway had been opened for a year, there is no doubt that the 300 members who then came to this City found their way here by the slow process of the stage-coach, the loss of which we so much deplore in the summer and in fine weather, but the obligatory use of which we should so much regret in the miserable weather now prevailing in these islands.

In 1881, we know that railways are everywhere inserted. Steel rails, double the weight of the original iron ones, are used. Wooden sleepers have replaced the stone blocks, and they, in their turn, will probably give way to sleepers of steel. The joints are now made by means of fish-plates, and the most vulnerable part of the rail, the end, is no longer laid on an anvil for a purpose of being smashed to pieces, but the ends of the rails are now almost always over a void, and thereby are not more affected by wear than is any other part of the rail. The speed is now from 50 to 60 miles an hour for passenger trains, while slow speed goods engines, weighing 45 tons, draw behind them coal trains of 800 tons. The injector is now commonly employed, and, by its aid, a careful driver of the engine of a stopping train can fill up his boiler while at rest at the stations. The link motion is in common use, to which, no doubt, is owing the very considerable economy with which the locomotive engine now works.

As regards the question of safety, it is a fact that, notwithstanding the increased speed, railway accidents are fewer than they were at the slow speed. It is also a fact that, if the whole population of London were to take a railway journey, there would be but one death arising out of it. Four millions of journeys for one death of a passenger from causes beyond his own control is, I believe, a state of security which rarely prevails elsewhere. As an instance, the street accidents in London alone cause between 200 and 300 deaths per annum. This safety in railway travelling is no doubt largely due to the block system, rendered possible by the electric telegraph; and also to the efficient interlocking of points and signals, which render it impossible now for a signalman to give an unsafe signal. He may give a wrong one, in the sense of inviting the wrong train to come in; but, although wrong in this sense, it would still be safe for that train to do so. If he can give a signal, that signal never invites to danger; before he can give it, every one of the signals, which can

to be "at danger," must be "at danger," and every "point" must have been previously set, so as to make the road right; then, again, we have the facing point-lock, which is a great source of safety.

Further, we have continuous brakes of various kinds, competent in practice to absorb three miles of speed in every second of time; that is to say, if a train were going 60 miles an hour, it can be pulled up in 20 seconds; or, if at the rate of 30 miles, in 10 seconds. With a train running at 50 miles an hour, it can be pulled up in from 15 to 20 seconds, and in a distance of from 180 to 240 yards. Moreover, in the event of the train separating into two or more sections, the brakes are automatically applied to each section, thereby bringing them to rest in a short time. Another cause of safety is undoubtedly the use of weldless tyres. I was fortunate enough to attend the British Association Meeting many years ago at Birmingham, and I then read a paper upon weldless tyres, in which I ventured to prophesy that, in ten years time, there would not be a welded tyre made; that is one of the few prophecies that, being made before the event, have been fulfilled. I may perhaps be permitted to mention, that at the same time I laid before the Section plans and suggestions for the making of the cylindrical parts of boilers equally without seam, or even welding. This is rarely done at the present time, but I am sure that, in twenty years time, such a thing as a longitudinal seam of rivets in a boiler will be unknown. There is no reason why the successive rings of boiler shells should not be made weldless, as tyres are now made weldless.

The next subject I intend to deal with is that of *Motors*. In 1831, we had the steam-engine, the water-wheel, the windmill, horse-power, manual power, and Stirling's hot-air engines. Gas engines, indeed, were proposed in 1824, but were not brought to the really practical stage. We had then tide mills; indeed, we have had them until quite lately, and it may be that some still exist; they were sources of economy in our fuel, and their abandonment, is to me a matter of regret. I remember tide mills on the coast between Brighton and Newhaven, another between Greenwich and Woolwich, another at Northfleet, and in many other places. Indeed, such mills were used pretty extensively; they were generally erected at the mouth of a stream, and in that way the river bed made the reservoir, and even when they were erected in other situations, those were of a kind suitable for the purpose, that is, low lying lands were selected, and were embanked to form reservoirs. In 1881, windmills and water-wheels are much the same, but the turbines are greatly improved, and by means of turbines we are enabled to make available the pressure derived from heads of water which formerly could not be used at all, or if used, involved the erection of enormous water-wheels, such as those at Glasgow and in the Isle of Man, wheels of some eighty feet in diameter. But now, by means of a small turbine, an excellent effect is produced from high heads of water. The same effect is obtained from the water-engines which our President has employed with such great success. In addition to these motors, we have the gas-engine, which, within the last few years only, has become a really useful working and economical machine. With

respect to horse-power motors, we have not, (by the old horse engines,) but we have a new application (as it seems to me, of the work of the horse as a motor. I allude to those cases where the horse drawing a reaping or threshing machine, not only pulls it forward as he might pull a cart, but causes its machinery to revolve so as to perform the desired kind of work. This species of horse-engine, though known, was but little used in 1831. With respect to hot-air engines, there have been many attempts to improve them, and some hot-air engines are working, and are working with considerable success; but the amount of power they develop in relation to their size is small, and I am inclined to doubt whether it can be much increased.

I now come to the subject of the *transmission of power*. I do not mean transmission in the ordinary sense by means of shafting, gearing, or belting, but I mean transmission over long distances. In 1831, we had for this purpose flat rods, as they were called, rods transmitting power from pumping engines for a considerable distance to the pits where the pumps were placed, and we had also the pneumatic, the exhaustion system—the invention of John Hague, a Yorkshireman, my old master, to whom I was apprenticed—which mode of transmission was then used to a very considerable extent. The recollection of it, I find, however, has nearly died out, and I am glad to have this opportunity of reviving it. But in 1881, we have, for the transmission of power, first of all, quick moving ropes, and there is not so far as I know, a better instance of this system than that at Schaffhausen. Anyone who has ever in recent years, gone a mile or two above the falls at Schaffhausen must have seen there—in a house on the bank of the Rhine, opposite to that at which the town is situated—large turbines driven by the river, which is slightly dammed up for the purpose. These work quick-going ropes, carried on pulleys, erected at intervals along the river bank, for the whole length of the town; and power is delivered from them to shafting below the streets, and from it into any house where it is required for manufacturing purposes. Then we have the compressed air transmission of power, which is very largely used for underground engines, and for the working of rock drills in mines and tunnels. We have also compressed air in a portable form, and it is now employed with great success in driving tram-cars. I had occasion last January to visit Nantes, where, for eighteen months, tram-cars had been driven by compressed air, carried in the cars themselves, coupled with an extremely ingenious arrangement for overcoming the difficulties commonly attendant on the use of compressed air engines. This consists in the provision of a cylindrical vessel half filled with hot water and half with steam, at a pressure of eighty pounds on the square inch. The compressed air, on its way from the reservoir to the engine, passes through the water and steam, becoming thereby heated and moistened, and in that way all the danger of forming ice in the cylinders was prevented, and the parts were susceptible of good lubrication. These cars, which start every ten minutes from each end, make a journey of 3½ miles, and have proved to be a commercial and an engineering success. I believe, moreover,

hat they are capable of very considerable improvement. Then there is, although not much used, the transmitting of power by means of long steam pipes. There is also the transmission hydraulically. This may be carried out in an intermittent manner, so as to replace the reciprocating flat rods of old days; that is to say, if two pipes containing water are laid down, and if the pressure in those pipes at the one end be alternated, there will be produced an alternating and a reciprocative effect at the other, to give motion to pumps or other machinery. There is also that thoroughly well known mode of transmission, hydraulically, for which the engineering world owes so much to our President. We have, by Sir William Armstrong's system, coupled with his accumulator, the means of transmitting hydraulically the power of a central motor to any place requiring it, and by the means of the principal accumulator, or if need be, by that aided by local accumulators, a comparatively small engine is enabled to meet very heavy demands made upon it for a short time. I think I am right in saying that, at the ordinary pressure which Sir William Armstrong uses in practice, viz., 700 lbs. to the square inch, one foot of motion along an inch pipe would deliver at the rate to produce one-horse power. Therefore, a ten-inch pipe, with the water traveling at no greater pace than three feet in a second, would deliver 300-horse power. This 300-horse power would no doubt be somewhat reduced by the loss in the hydraulic engine, which would utilise the water. But the total energy received would be equivalent to producing 300-horse power. Such a transmission would be effected with an exceedingly small loss in friction in transit. I believe I am right in saying that a 10-inch pipe a mile long would not involve much more than about 14 or 15 lbs. differential pressure to propel the water through it at a rate of three feet in a second. If that be so, then, with 700 lbs. to the inch, the loss under such circumstances would be only two per cent. in transmission. There is no doubt that this transmission of power hydraulically has been of the greatest possible use. It has enabled work to be done which could not be done before. Enormous weights are raised with facility wherever required, as by the aid of power hydraulically transmitted, it is perfectly easy for one man to manage the heaviest cranes. Moreover, as I have said in other places, the system which we owe to Sir William Armstrong has gone far to elevate the human race, and it has done so in this manner. So long as it is competent for a man to earn a living by mere unintelligent exercise of his muscles, he is very likely to do it. You may see in the old London docks the crane-heads covered by structures that look like paddle-boxes. If you go to them, there is, I am glad to say, nothing now to fill them up; but when the British Association first met, these paddle-boxes covered large tread-wheels, in which the men trod, so as to raise a weight. Now, although I know that in fact there is nothing more objectionable in a man turning a wheel by treading inside of it than there is if he turn it round by a winch-handle, yet somehow it strikes one more as being merely the work of an animal, a turnspit, or a squirrel, or indeed as the task imposed on the criminal. But, neverthe-

less, in this way there were a large number of persons getting their living by the mere exercise of their muscles, but, as might be expected, a very poor living, derived as it was from unintelligent labour. That work is no longer possible, and is not so, for the powerful reason that it does not pay. Those persons, therefore, who would now have been thus occupied, are compelled to elevate themselves, and to become competent to earn their living in a manner which is more worthy of an intelligent human being. It is on these grounds that I say we owe very much the elevation of the working classes, especially of the class below the artisan, to this invention of our distinguished President. In addition to the modes of transmission I have already mentioned, there is the transmission of power by means of gas. I think that there is a very large future indeed for gas engines. I do not know whether this may be the place to state it, but I believe the way in which we shall utilise our fuel hereafter will, in all probability, not be by the way of the steam-engine. Sir William Armstrong alluded to this probability in his address, and I entirely agree, if he will allow me to say so, that such a change in the production of power from fuel appears to be impending, if not in the immediate future, at all events in a time not very far remote; and however much the Mechanical Section of the British Association may to-day contemplate with regret, even the mere distant prospect of the steam-engine being a thing of the past, I very much doubt whether those who meet here fifty years hence will then speak of it as anything more than a curiosity to be found in a museum. With respect to the transmission of power electrically, I won't venture to touch upon that; but will content myself by reminding you that while Sir William Armstrong did say that there were comparatively small streams which could be utilised, he did not inform you of that which he himself had done in this direction; let me say that Sir William Armstrong thus utilised a fall of water, situated about a mile from his house, to work a turbine, which drives a dynamo machine, generating electricity, for the illumination of the house. When I was last at Crag Side, that illumination was being effected by the arc light, but since then, as Sir William Armstrong has been good enough to write to me, he has replaced the arc light by the incandescent lamp (a form of electrical lighting far more applicable than the arc light to domestic purposes), and with the greatest possible success. Thus, in Sir William Armstrong's own case, a small stream is made to afford light in a dwelling a mile away. Certainly nothing could have seemed more improbable fifty years ago than that the light of a house should be derived from a fall of water without the employment of any kind or description of fuel.

The next subject upon which I propose to touch, is that of the *Manufacture of iron and the steel*. In 1831, Neilson's hot blast specification had been published for 2½ years only. The Buttery Company had tried the hot blast for the first time in the November preceding the meeting of the British Association. The heating of the blast was coming very slowly into use, and the tem-

Mr. E. A. Cowper's stoves—is at 1,200 degrees. The manufacture of iron has also now enlisted in its service the chemist as well as the engineer, and amongst those who have done much for the improvement of the blast furnaces, to no one is greater praise due than to Mr. Isaac Lowthian Bell, who has brought the manufacture of iron to the position of a highly scientific operation. In the production of wrought iron by the puddling process, and in the subsequent mill operations, there is no very considerable change, except in the magnitude of the machines employed, and in the greater rapidity with which they now run. In saying this, I am not forgetting the various "mechanical puddlers" which have been put to work, nor the attempts that have been made by the use of some of them to make wrought iron direct from the ore; but neither the "mechanical puddler" nor the "direct process" have yet come into general use; and I desire to be taken as speaking of that which is the ordinary process pursued at the present in puddled iron manufactures. In 1831, a few hundred weights was the limit of weight of a plate, while in 1881, there may readily be obtained, for boiler-making purposes, plates of at least four times the weight of those that were made in 1831. I may, perhaps, be allowed to say that there is an extremely interesting Blue-book of the year 1818, containing the report of a Parliamentary Committee which sat on boiler explosions, and I recommend any mechanical engineer who is interested in the history of the subject to read that book; he will find it there stated that in the North of England there were a species of engines called locomotives, the boilers of which were made of wrought iron beaten, not rolled, because the rolled plate was not considered fit; it was added that if made of beaten iron the boiler would last at least a year. In 1831, thirteen years later, the dimensions of rolled plates were no doubt raised; but few then would have supposed it possible there should be

known as early as the present time ago it alone was used. With 1831, the process in use was producing blistered steel, which was welded to make shear into small pieces, melted in ingot weighing only some 5 that time, steel was dealt in by thought of steel in tons. aware that, by Sir Henry Bessemer's discovery, carried out by him with vigour, cast-iron is, by the converted into steel, and that, by the well-known process (now that tion of the regenerative furnace) obtain the necessary high temperature made upon the open hearth. aware that, by both of these processes produced in quantities of in operation, with the result in the case of the North is a cheaper material than made by the puddling process away from the steel manufacture to Sir Joseph Whitworth's pressure on the steel while in this means, the cavities which found in the ingot of a large size is fluid, rendered considerably is thereby rendered much more solid. In my observations on the steel manufacture, I wish to mention the invention of Messrs. Thomas which ores of iron, containing phosphorus, fitted them to be used in the engines are now freed from these impurities brought into use for steel-making. Bridges.—In the year 1831, existed; but no attempt had been made to use wrought iron in girder bridges had employed it in the Menai but in 1881, the introduction of the Bessemer improvement in iron manufacture

ould have been needed if no wind had aken into account, and if the question of iple weight to be carried had alone to be sed. With respect to the foundation of , that ingenious man, Lord Cochrane, d a mode of sinking foundations, even before meeting of the British Association, viz., as far believe, as 1825 or 1826; and the improve- hich he then invented are almost universally in bridge construction at the present day. rs sunk by the aid of compressed air, air- obtain access to the cylinder, and in fact every that I know of as having been used in the sinking of cylinder foundations, were d by Lord Cochrane (afterwards Earl of ald) in that specification.

ext subject I propose to touch on, is that ine Tools. In 1831, the mention of lathes, machines, and screwing machines, brings r nearly to the end of the list of the tools used by turners and fitters, and at e many lathes were without slide rests. erner-maker had then his punching-press and machine; the smith, leaving on one side s and their bellows, had nothing but hand d the limit of these was a huge hammer, handles, requiring two men to work it. or manufacture, it is true, a mechanical mmer, known as a Hercules, was employed, iron works, the Helve and the Tilt ham- re in use. For ordinary smith's work, e, there were, as has been said, practically ine tools at all.

paucity or absence in some trades, as we en, of machine tools, involved the need of siderable skill on the part of the work- It required the smith to be a man not great muscular power, but to be possessed accurate eye and a correct judgment, in o produce the forgings which were de- l of him, and to make the sound work that eded, especially when that soundness was d in shafts, and in other pieces which, in lays, were looked upon as of magnitude; indeed, they were, relatively to the tools could be brought to operate upon them. iler-maker in his work had to trust almost r to the eye for correctness of form and for ity of punching, while all parts of engines chines which could not be dealt with in the, in the drilling, or in the screwing e, had to be prepared by the use of the and the file.

ne present day, the turning and fitting shops nished, not only with the slide lathe, self- in both directions, and screw-cutting, the ; machine, and the screwing machine, but aning machines competent to plane hori- y, vertically, or at an angle; shaping es, rapidly reciprocating, and dealing with any form of work; nut-shaping machines, illing machines, and slotting machines, he drills have become multiple and radial; e accuracy of the work is ensured by testing e surface plates, and by the employment of orth internal and external standard gauges. boiler-maker's tools now comprise the steam, essed air, hydraulic or other mechanical r, rolls for the bending of plates while cold e needed cylindrical or conical forms,

multiple drills for the drilling of rivet holes, planing machines to plane the edges of the plates, ingenious apparatus for flanging them, there- by dispensing with one row of rivets out of two, and roller expanders for expanding the tubes in loco- motive and in marine boilers; while the punching press, where still used, is improved so as to make the holes for seams of rivets in a perfect line, and with absolute accuracy of pitch.

With respect to the smith's shop, all large pieces of work are now manipulated under heavy Nasmyth or other steam hammers; while smaller pieces of work are commonly prepared either in forging machines or under rapidly moving hammers, and when needed in sufficient numbers are made in dies. And applicable to all the three industries of the fitting shop, the boiler shop, and the smith's shop, and also to that other industry carried on in the foundry, are the travelling and swing cranes, commonly worked by shafting, or by quick moving ropes for the travellers, and by hydraulic power or by steam-engines for the swing cranes. It may safely be said that, without the aid of these imple- ments, it would be impossible to handle the weights that are met with in machinery of the present day.

I now come to one class of machine which, humble and small as it is, has probably had a greater effect upon industry and upon domestic life than almost any other. I mean the *Sewing machine*. In 1831, there was no means of making a seam except by the laborious process of the hand needle. In 1846, Eldred Walker patented a machine for passing the basting thread through the gores of umbrellas, a machine that was very ingenious and very simple, but was utterly unlike the present sewing machine, with its eye-pointed needle, using sometimes two threads (the second being put in by a shuttle or by another needle), and making stitches at twenty-fold, the rapidity with which the most expert needle- woman could work. By means of the sewing machine not only are all textile fabrics operated upon, but even the thickest leather is dealt with, and as a *tour de force*, but as a matter of fact, sheet-iron plates themselves have been pierced, and have been united by a seam no boiler-maker ever contemplated, the piercing and the seam being produced by a Blake sewing machine. I believe all in this Section will agree that the use of the sewing machine has been unattended by loss to those who earn their living by the needle; in fact, it would not be too much to say that there has been a positive improvement in their wages.

The next matter I have to touch upon is *Agricultural machinery*. In 1831, we had threshing machines and double ploughs, and even multiple ploughs had been proposed, tried, and abandoned. Reaping machines had been experimented with and abandoned; sowing machines were in use, but not many of them; clod crushers and horse rakes were also in use; but as a fact ploughing was done by horse power with a single furrow at a time, mowing and reaping were done by the scythe or the sickle, sheaves were bound by hand, hay was tedded by hand-rakes, while all materials and produce were moved about in carts and in waggons drawn by horses. At the present time we have multiple ploughs, making five or six furrows at a time, these and cultivators also driven by steam, commonly from two engines on the head lands, the plough being in between, and worked by

a rope from each engine, or if by one engine, a capstan on the other head land, with a return rope working the plough backwards and forwards; or by what is known as the round-about system, where the engine is fixed and the rope carried round about the field; or else ploughs and cultivators are worked by ropes from two capstans placed on the two head lands, and driven by means of a quick going rope, actuated by an engine, the position of which is not changed. And then we have reaping machines, driven at present by horses; but how long it will be before the energy residing in a battery, or that in a reservoir of compressed air, will supersede horse power to drive the reaping machine, I don't know, but I don't suppose it will be very long. The mowing and reaping machines not only cut the crop and distribute it in swathes, or, in the case of the reaping machine, in bundles, but now, in the instance of these latter machines, are competent to bind it into sheaves. In lieu of hand tedding, hay-making machines are employed, tossing the grass into the air, so as to thoroughly aerate it, taking advantage of every brief interval of fine weather; and seed and manure are distributed by machine with unerring accuracy. The soil is drained by the aid of properly constructed ploughs for preparing the trenches; roots are steamed and sliced as food for cattle; and the threshing machine no longer merely beats out the grain, but it screens it, separates it, and elevates the straw, so as to mechanically build it up into a stack. I do not know a better class of machine than the agricultural portable engine. Every part of it is perfectly proportioned and made, it is usually of the locomotive type, and the economy of fuel in its use is extremely great. I cannot help thinking that the improvement in this respect which has taken place in these engines, and the improvement of agricultural machinery generally, is very largely due to the Royal Agricultural Society, one of the most enterprising bodies in England.

I now come to the very last subject I propose to speak upon, and that is *Printing machinery*, and especially as applied to the printing of newspapers. In 1831, we had the steam press sending out a few hundred copies in an hour, and doing that upon detached sheets, and thus many hours were required for an edition of some thousands. The only way of expediting the matter would have been to have recomposed the paper, involving, however, double labour to the compositors, and a double chance of error. At the present day, we have, by the *Walter press*, the paper printed on a continuous sheet at a rate per hour at least three times as great as that of the presses of 1831, and, by the aid of *papier maché* moulds, within five minutes from the starting of the first press, a second press can be got to work from the stereotype plates, and a third one in the next five minutes; and thus the wisdom of our senators, which has been delivered as late as three o'clock in the morning, is able to be transmitted by the newspaper train leaving Euston at 5.15 a.m.

This is the last matter with which I shall trouble the Section. I have purposely omitted telegraphy; I have purposely omitted artillery, textile fabrics, and the milling and preparation of grain. These and other matters I have omitted for several

reasons. Some I have omitted because incompetent to speak upon them, others because the want of time, and others because they properly belong to Section A.

I hope, sir, although your address, dated the future, was undoubtedly the right one for a President to deliver, and although it is right that we should not content ourselves merely looking back in a "rest and be thankful" spirit at the various progress which the records, it may nevertheless be thought where there should have been brought before the in however cursory a manner, some of the mechanical development during the past fifty

## GENERAL NOTES.

**Vienna Art Exhibition.**—An International Exhibition of the chief works of art produced since the Exhibition of 1873 will be opened at Vienna, by the Vienna Artists, on April 1, 1882, and continue open until the 30th. The Exhibition will comprise architectural models, paintings, engravings, and sculpture. All intended for exhibition must be delivered at the Museum, Vienna, not later than March 1, 1882.

**Patent Medicines.**—According to a return just issued the number of licences to sell patent medicines during the year ending the 31st of March last was 11, for which there was paid the sum of £4,000. The revenue derived from stamps for patent medicines the same time amounted to £139,762 18s. 10d. and represented 17,190,442 stamps of different values.

**"The Glow" Stove.**—An open slow combustion stove on a new principle has recently been put forward by Messrs. Everitt and Bernard, and will be exhibited at the Society's Smoke Abatement Exhibition, to be held at the South Kensington Museum this month. The stove is in all slow combustion stoves, is closed in front, the front is a number of holes, carrying a gas pipe beneath and parallel with the surface upon which the fuel is placed. These openings are connected with an air duct at the back of the grate, which chamber has an outlet directly over the fuel. A "Baffle" of fire brick, the front and about an inch above the openings from the grate, extends the full width of the stove, springing the back at an angle of about 80°. The object of the "Baffle," which becomes red-hot, is to form a chamber in which smoke is consumed, to arrest heat which would otherwise escape up the chimney, and throw the accumulated heat into the room.

## MEETINGS FOR THE ENSUING WEEK.

**MONDAY, Nov. 7.** Farmers' Club, Lane of Court Hotel, 1 W.C., 4 p.m. Mr. G. M. Allender, "Dairies."

**TUESDAY, Nov. 8.** Central Chamber of Commerce (at the request of the Society of Arts), 11 a.m.

Medical and Chirurgical, 52, Berners-street, W., 8.30 p.m.

Civil Engineers, 25, Great George-street, W., 8 p.m. Mr. Charles Wood, "Iron Pipe."

Anthropological Institute, 4, St. Martin's-place, 8 p.m. 1. Mr. E. F. M. Thurn, "The American Indians of British Guiana." 2. Mr. M. J. W. "Some Vestiges of Old Civilisation, Jan. 1881." 3. Mr. B. Wills Richardson, "Multiple Cloning of and Vegetable Tumours."

**WEDNESDAY, Nov. 9.** Microscopical, King's College, W., 8 p.m. Mr. B. Wills Richardson, "Multiple Cloning of and Vegetable Tumours."

**THURSDAY, Nov. 10.** Mathematical, 22, Albemarle-street, 8 p.m. 1. Annual Meeting of the Society of Arts. 2. Mr. W. Merrifield, "Note on the Limit to the of Proper Fractions, &c." 3. Prof. H. Lamb, "On the Oscillations of a Viscous Spheroid."

**FRIDAY, Nov. 11.** Physical Science, South Kensington, 3 p.m. 1. Mr. Lewis Wright, "On Crystals." 2. Mr. C. V. Boys, "Laboratory Apparatus for the Measurement of Small Mechanical Forces."

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,512. Vol. XXIX.

FRIDAY, NOVEMBER 11, 1881.

*All communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## PATENT LAW DISCUSSION.

The Discussion on the Society of Arts' Patent Bill will not be held on Wednesday, November 30, as previously announced, but on Friday, December 2nd.

The discussion will be opened by Sir FREDERICK BRAMWELL, F.R.S., Chairman of the Council, and will be continued on such evenings as may be found convenient.

The Secretary will be glad to furnish tickets for the meeting to persons interested in the subject of Patent Law who are not members of the Society.

## ELECTRIC LIGHTING IN THEATRES.

Mr. R. D'Oyly Carte, the proprietor of the Savoy Theatre, in the Strand, has kindly made arrangements for Members of the Society, who may wish to do so, to inspect the lighting arrangements of the Savoy Theatre, on the afternoon of to-morrow (Saturday, the 12th of November), at ten minutes before five. Members will be admitted on presentation of their visiting cards. Each member may be accompanied by one friend.

## EXHIBITION OF PHOTOGRAPHIC APPLIANCES.

In connexion with the course of Cantor Lectures, which will be delivered by Captain Abney, F.R.S., on "Recent Advances in Photography," in January and February next, it is proposed to hold, in the House of the Society of Arts, an Exhibition of Photographic Appliances.

The dates of Captain Abney's Lectures are January 30, February 6, 13, and 20. The Exhibition will be kept open from January 30 till about the end of February.

The Exhibition will be of a technical character, and it is not, therefore, desired to collect photographs of artistic merit only.

The following are among the principal classes of objects sought for exhibition :—

Apparatus: cameras, lenses, tents, instantaneous shutters, slides, sensitometers, lamps (intended specially for photographic purposes), enlarging apparatus, printing and mounting apparatus, &c.

Photographic materials.

Illustrations of new processes; negatives and prints produced by new or special processes.

Appliances used in reproductive processes; specimens of illustrations produced by such processes; specimens of historical interest, as illustrations of old processes.

Lighting: models illustrative of characteristic features in the construction of glass houses; methods of fixing glass without putty or similar material; arrangements for the production of artificial light for photographic purposes.

Any person wishing to exhibit any of the above is requested to communicate with the Secretary of the Society, who will supply printed forms of application for space, and will be glad to give any further information required.

It is hoped that arrangements may be made for showing the actual working of some of the more recent processes.

## LABEL FOR PLANTS.

The Council, on the recommendation of the judges in the late competition of plant labels, are prepared to renew the offer of a Society's Silver Medal, together with a prize of £5, which has been placed at their disposal for the purpose by Mr. G. F. Wilson, F.R.S., for the best label for plants.

The object of the offer is to obtain a label which may be cheap and durable, and may show legibly whatever is written or printed thereon; the label must be suitable for plants in open border. These considerations will principally govern the award.

The award will be made on the recommendation of the Committee appointed for the purpose by the Council.

Specimen labels, bearing a number or motto, and accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary of the Society, not later than the 1st May, 1882.

The Council reserve to themselves the right of withholding medal and prize offered, if, in the opinion of the judges, none of the specimens sent in are deserving.

**ARRANGEMENTS FOR THE SESSION.**

The first meeting of the One Hundred and Twenty-eighth Session of the Society will be held on Wednesday, the 16th inst., when the Opening Address will be delivered by Sir FREDERICK J. BRAMWELL, F.R.S., Chairman of the Council, and the Medals awarded during the last Session will be presented. Previous to Christmas, there will be four ordinary meetings in addition to the opening meeting.

Candidates proposed for election as members are privileged to attend the opening meeting.

**ORDINARY MEETINGS.**

The following arrangements for the Wednesday evenings before Christmas have been made:—

**NOVEMBER 16.**—Opening Meeting of the Session. Address by Sir FREDERICK J. BRAMWELL, F.R.S., Chairman of the Council.

**NOVEMBER 23.**—"The Storage of Electricity." By Prof. SYLVANUS THOMPSON, D.Sc.

**NOVEMBER 30.**—"The Distribution of Time by a System of Pneumatic Clocks." By J. A. BEELY.

**DECEMBER 7.**—"The American System of Heating Towns by Steam." By Capt. DOUGLAS GALTON, C.B., F.R.S.

**DECEMBER 14.**—"Electric Lighting at the Paris Electrical Exhibition." By W. H. PREECE, F.R.S.

At the meetings after Christmas, the following papers (among others) will be read:—

"Practical Hints on the Manufacture of Gelatine Emulsions and Plates for Photographic Purposes." By W. K. BURTON.

"Stained Glass Windows." By LEWIS FOREMAN DAY.

"Photometric Standards." By HAROLD DIXON.

"Telephonic Communication." By LIEUT.-COL. C. E. WEBBER.

"The Causes and Remedies of Bad Trade." By WALTER R. BROWNE, M.A.

"The Native Tribes of the Hudson's Bay Territories." By Dr. RAE, F.R.S.

"The Manufacture of Ordnance." By COLONEL MANTLAND.

"Some Practical Aspects of Recent Investigations in Nitrification." By R. WARINGTON.

"The Production and Use of Gas for Purposes of Heating and Motive Power." By J. EMERSON DOWSON.

"Gas for Lighthouses." (Illustrated by an exhibition of some of the gas flames and apparatus used in lighthouses.) By JOHN WIGHAM.

"The Relation of Botanical Science to Ornamental Art." By F. EDWARD HULME, F.L.S., F.S.A.

"The High-pressure Steam-engine." By LOFTUS PERKINS.

"The Industrial Resources of Ireland." By G. PHILLIPS BEVAN.

"A New Antiseptic Compound, and its Application to the Preservation of Food." By Prof. BARNY, M.A.

"Tonnage Measurement." By ADMIRAL SIR R. SPENCER ROBINSON, K.C.B., F.R.S.

"Tools and Cutting Edges." By D. A. ARM.  
"The Teaching of Forestry." By COLONEL G. I. PEARSON.

"The Art of Turning." By P. W. HASLUCK.

**FOREIGN AND COLONIAL SECTION.**

The meetings of this Section will take place on the following Tuesday Evenings, at Eight o'clock:—

January 31; February 28; March 21; April 4; May 23.

**APPLIED CHEMISTRY AND PHYSICS SECTION**

The meetings of this Section will take place on the following Thursday Evenings, at Eight o'clock:—

January 26; February 23; March 9, 30; April May 11.

**INDIAN SECTION.**

The meetings of this Section will take place on the following Friday Evenings, at Eight o'clock:—

February 17; March 17, 31; April 21; May 12.

**CANTOR LECTURES.**

The First Course will be on "Some of Industrial Uses of the Calcium Compounds." THOMAS BOLAS, F.C.S.

November 21, 28; December 5, 12.

The Second Course will be on "Recent Advances in Photography." By CAPT. ARNEY, R.E., F.R.S.  
January 30; February 6, 13, 20.

The Third Course will be on "Hydraulic Machinery." By PROF. JOHN PERRY.  
March 6, 13, 20, 27.

The Fourth Course will be on "Book Illustration, Old and New." By J. COMYNS CARR.  
April 20; May 1, 8, 15.

*Syllabus of the First Course.***LECTURE I.**

Distribution and occurrence of calcium in nature. Carbonate of lime as limestone, chalk, marble, calcareous shells, &c. Notes on some of the calcium minerals. Short survey of the chemistry of calcium and its derivations.

**LECTURE II.**

Lime. The calcination of the carbonate in nature and practice. Influence of foreign bodies on quality of the lime. Most favourable conditions for decomposition of pure and impure forms of calcium carbonate. Cements and their uses. Lime as refractory material. Lime-light. The oxyhydrogen furnace. Lime moulds for the casting of iron and steel. Notes on a few of the industrial and domestic uses of lime.

## LECTURE III.

Sulphate of lime and its occurrence in nature. Gypsum and alabaster. Plaster of Paris, its preparation and uses. Physical and chemical aspects of the setting of plaster. Accelerating and retarding influences. Scientific principles involved in some of the applications of plaster. Moulding, stereotyping, and other processes.

## LECTURE IV.

Other calcium compounds and their uses. The phosphorescent sulphide. Lime soaps. Bleaching powder. Phosphates of calcium. Organic calcine salts. The hardness of water, &c.

## JUVENILE LECTURES.

The two Juvenile Lectures will be by W. H. PREECE, F.R.S., on "Recent Wonders of Electricity." The dates for these are Wednesday evenings, December 28 and January 4. The Lectures will commence at 7 o'clock.

Special tickets will be issued for these lectures, due announcement of which will be made.

## ADMISSION TO MEETINGS.

Members have the right of attending all the Society's meetings and lectures. They require no tickets (except for the Juvenile Lectures), but are admitted on signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor Lectures. Books of tickets for the purpose have been issued to the Members, but admission can also be obtained on the personal introduction of a Member.

## ANNUAL GENERAL MEETING.

The Annual General Meeting will be held on Wednesday, June 28, at four o'clock.

The following is a table of dates of the Evening Meetings of the Society, subject to such alteration as may be found necessary:—

	CANTOR LECTURES.	FOREIGN AND COLONIAL MEETINGS.	ORDINARY MEETINGS.	APPLIED CHEMISTRY AND PHYSICS MEETINGS.	INDIAN MEETINGS.
	Monday.	Tuesday.	Wednesday.	Thursday.	Friday.
1881.

THE CHAIR WILL BE TAKEN AT EIGHT O'CLOCK AT EACH OF THE ABOVE MEETINGS.

## MISCELLANEOUS.

## THE CULTIVATION OF THE RAMEH PLANT.

The rameh plant possesses qualities and merits of the highest value for textile industries, and in the whole of Europe, Consul Stanton states, that France alone has attempted the industrial development of this Chinese plant, and the attempt has met with such success as to give that country a decided advantage over other European manufacturing countries. At the present time the cultivation makes great progress in Southern France, Corsica, and Algiers, and a practical process has lately been discovered for separating the fibres from the stems. The plant belongs to the nettle family, and although stingless, is similar to the stinging nettle in the form both of its leaves and branches, having, however, a much more luxuriant growth. The branches grow straight, and in bunches, and are composed of a brittle, woody substance, filled with pith, and surrounded with a fibrous covering which, in its

turn, is covered with a thin skin or rind. The fibres are bound together by a resinous substance, which is more difficult to dissolve than that contained in flax and hemp, and from this circumstance the setting of the rameh plant is more laborious than hemp and flax, though the hankling of the stems is less arduous. The propagation of the plant may be effected by seeds, layers, or cuttings; but as the reproduction from seeds is generally slow and uncertain, slips and layers are more often used. The rameh is a perennial, and not like flax and hemp, an annual, and its strength and fertility increases with its age; it withstands both drought and damp, but is very susceptible to frost. Even after frost, however, it is only the first crop which is lost, since the roots, which penetrate the ground to a depth of about a foot, are seldom affected, and soon put forth new shoots. Its growth is unusually rapid, and even in France it attains annually a height of from six to eight feet. In its home, however (China and Bengal), it attains the height of 15 feet. By cutting the stems when they have attained a height of three feet, several crops and finer fibres are obtained, the plant renewing its shoots continually. The leaves, when dried, are valuable for the manufacture of the tough paper which is so

tensively used in China, while the green ones afford excellent cattle fodder. On account of its luxuriant growth, extensive manuring is requisite; and, with the exception of this manuring, and the careful manner in which it must be done, the cultivation of the rameh is of the simplest kind, and with due care for frost, it may be planted at any season. The planting is generally in furrow, ten inches deep, and a yard apart, the plants being set out at intervals of a yard. Hoeing and digging are only necessary the first year, the plant growing afterwards with such luxuriance as to smother all weeds. In the spring, and after each cutting, hoeing is generally resorted to; and if, at the approach of winter, the earth is heaped up round the roots, to protect them from frost, the branches increase rapidly in number, the first growth yielding from three to four, the second from six to eight, the third from ten to twelve, and the fourth (this, however, is only in warm climates), from sixteen to twenty branches. The pecuniary results so far obtained, are most satisfactory. It is maintained that the rameh plant will yield a crop worth from £56 to £80 per hectare (2·47 acres); and assuming that three cuttings are annually obtained, there would be a yield of from 4,000 to 5,000 kilos. of leaves alone, which would cover all the expenses of cultivation. In addition to this, there would be from 1,500 to 2,200 kilos. of fibres, from which 1,200 to 1,500 kilos. of white linen could be spun. The tenacity of the rameh fibre is 30 per cent. greater than that of flax, and in consequence of this tenacity, it has for many years been used in China in the manufacture of many articles, in which solidity is absolutely necessary. In China from fibres of this plant the coarsest nets are woven, and fabrics which surpass in gloss and delicacy the finest battiste. As with flax and hemp, the first operation is to separate the fibres from the resinous substance which unites them; this is effected by steeping in water. The Belgians have recently substituted for the old plan, a new, more rapid, and healthier process, which produces an excellent commercial result. Large square cemented vats are used; in these the branches are laid, then water is poured on and kept, for flax and hemp, for one or two days, and for rameh from five to six days; to the water one-half per cent. of the weight of the branches, of pulverised charcoal is added, and the same quantity of carbonate of soda or potash, and throughout the process the vats are kept carefully closed. In this manner decomposition takes place slowly, and the fibres are protected from the injurious effects of the exhalations of sulphureted hydrogen. After the gluten is dissolved from the fibres, they have only to be separated from the woody tissue; this is effected by hackling, which was formerly slowly and arduously done by hand, but is now performed by machinery in a very simple manner. The branches are passed successively through four pairs of rollers, which destroy the woody tissue; then the hackling is done by two pairs of grooved cylinders, which, by a movement backwards and forwards, rub and cleanse the fibres from all impurities; a third machine, which consists of a hollow cylinder inclosing an axle, does the combing. This axle is provided with a number of whips, which beat the fibres continually; the fibres enter the cylinder at an opening in the side, the dust is removed by a ventilator, and the branches reduced to the finest fibres, leave the machine perfectly cleansed, and after bleaching are ready for spinning. In consequence of the silky character of the fibre, it is necessary to fasten the warp securely to prevent its being pulled out when weaving. Special attention is also paid to the dyeing to ensure fast colours. In France, measures have been taken for the manufacture of elegant rameh stuffs on a large scale, either from rameh for table-cloths, and furniture coverings, or mixed with wool and silk for draperies, and it is the opinion of those engaged in the manufacture of textile fabrics that the time has arrived when this material will play a great rôle in textile industries.

## CORRESPONDENCE.

### PISTACHIA GUM.

Some time ago I read in your *Journal* (vol. xxix, p. 596), that Mr. Thos. Christy, F.L.S., offered to supply any of your readers with samples of a new gum called *Pistachia terebinthus*, so that its value as an article of commerce might be tested. Having procured a sample of this gum, I will now, if you have space to spare in your valuable *Journal*, give you a few particulars as to my experiments with it, which will prove, in my opinion, its future commercial value.

This new gum, which is soluble in oil, turpentine, and alcohol, is of a light yellowish colour, and has an agreeable odour of mastic.

If the *Pistachia* gum is mixed with common resin, soda of a strength of 25 degrees has no soluble action on the gum, and soda of a strength even far greater than 25 degrees has, no more than water, any effect on the unadulterated *Pistachia* gum. These facts alone are a sufficient proof of the value of this gum for the uses to which I have subjected it in my experiments.

It is well known that most of the gums or resins now used in the manufacture of varnish are soluble in soda, and therefore yield to the action of soap in a short space of time. Now, the varnish made with *Pistachia* gum possesses many advantages over the ordinary varnish, for, besides being waterproof, it does not in any way yield to either the action of soap or soda, and it can also be advantageously used for oilcloth.

I found, after further experiment, that when left in contact with the open air, this new varnish thickens very quickly, which renders it a valuable acquisition to painters on glass and porcelain, both as a substitute for the burning process, or to mix with the colours now used.

The colour of this varnish can be made of different shades, varying from a light grey to a beautiful dark brown, and it has the same appearance as the ordinary varnish. *Pistachia* gum, while of a similar character and of the same basis as Venetian turpentine, is far more important in its composition, which ought to render it valuable for commercial and medicinal purposes, and I may add, in conclusion, that *Pistachia terebinthus* gum, as a varnish and paint, in my opinion will become in the future of great value for these purposes.

JULES GRETT.

Ponder's-end.

### SCIENCE TEACHING IN SCHOOLS.

The following may interest the readers of the *Society of Arts' Journal*, as affording a practical illustration of the ease with which the elementary scientific notions that have the most direct bearing on daily life, may be introduced in the schools of the people.

The views I had long entertained concerning the introduction of useful knowledge in the education of the masses, received in 1870 much encouragement from the adoption, by the London School Board, of Dr. Gladstone's plan for initiating, at an early age, by experimental as well as visual means, elementary notions about Common Things, and disseminating practical germs of thoughtful cleverness. I naturally became anxious to show how conveniently the materials for progressive lessons in physics, chemistry, and physiology, contained in my "*Science made Easy*," Course of ten lectures, might serve for developing in the successive standards of primary schools knowledge conducive to health, common sense, and industrial success. In order to indicate how this might be done most effectually, I invited the teachers of both sexes of the Metropolitan Board Schools to attend, in the beginning

of 1880, a special delivery of the courses. By permission of the head-master, Dr. Wormell, it was given at the Middle-Class Schools in Cowper-street, where a full collection of my apparatus and diagrams was in constant use by Mr. J. Bower, one of the science masters, who added appropriate pedagogic remarks and advice. The attendance of the teachers was numerous, and their satisfaction very encouraging, as was also the manner in which a considerable number of them passed a special examination held on the so-called "open-handed" system.

My next step was to place a collection of "Science made Easy" apparatus and diagrams at the disposal of the London School Board, for being circulated seriatim, by way of experiment, to seven Board schools in various parts of the metropolis, duly supplied with copies of the ten lectures, and with "Suggestions" in a pamphlet form, for their adaptation to juvenile instruction. Each school in its turn has the use of a lecture-box for at least a fortnight, at the end of which term the multifarious contents are inspected by my special agent, cleaned, replenished and packed for being transmitted to the school next on the list. The scheme may seem an intricate one, but it is progressing admirably, thanks to the intelligent management of my secretary, who, from the Economic Museum, directs each detail of the proceedings; and to the exemplary promptness and regularity with which the Stores Department of the School Board effects the transfer of the boxes from school to school.

Though the experiment is not yet entirely completed, it has become evident that, should the London School Board be inclined to follow up the system thus initiated, a comparatively limited number of "Science made Easy" sets would suffice to meet the requirements of the chief schools of the metropolis. They might be supplied by Messrs. Griffin, of Garrick-street, Covent-garden, who have lately completed a pattern set for the American Government, and who would contract for the periodical inspection and renovation at a charge which, according to my experience, would be moderate. A far more important point, however, is the satisfaction with which the masters appear to dispense this practical instruction, and the pleasure with which the children appear to receive it. I cannot do better than quote on this score a letter just received from the head master of one of the schools, which, being among the first on the list, has completed the use of the course:—

"The masters (including myself) liked the lessons very much, and the boys looked forward to them, so much so, that we had the highest attendance on the days the lessons were given, and it was considered a severe punishment to be sent into another room, and thus lose the science lessons. . . . Thanking you very much for the opportunity you have placed in my way of having pleasing, useful lessons, so admirably illustrated, given in my school, I remain, yours, &c."

It is essential to make a clear distinction between a system of *connected* and progressive lessons, carefully selected with a view to practical utility, from the general range of natural science, and the plan which has hitherto prevailed, of teaching *detached* branches of science as "special subjects," with a view, perhaps, rather to the best chances of pecuniary results, than to the prospective occupations, and consequent requirements of the children. Special attainments in science and art need not be excluded in the highest standards, but they are best acquired in that secondary instruction to which so much attention is being devoted, among the more enlightened of the industrial communities of the Continent, and which amongst us is mainly represented by Evening Classes. This secondary instruction in science should diverge freely into the various channels of industrial employment. Primary science, on the contrary, whilst it should serve as a general foundation to special secondary attainments, should at the same

time consist of information directly meeting the requirements of Daily Life; it should, in fact, precisely teach that knowledge which everyone ought to possess; and, accordingly, making allowance for certain natural distinctions of sex, and for a few differences depending on local circumstances, or deficient resources it should be *obligatory* and *uniform*. It should be moulded on an official programme, prepared by thoroughly competent educationalists, which would indicate, with elastic outlines, the course to be pursued, and supply alternatives for abnormal circumstances.

T. TWINKING.

Twickenham.

## BOILERS OF KITCHENERS.

As householders are now beginning to look forward to the winter with its consequent frosts, and as the old-fashioned kitchen ranges are being entirely superseded by the modern kitchener, it seems to me very desirable that the use of these should be properly and thoroughly understood. I find that in the ordinary dwelling houses now being built, or those of recent construction, the *double oven* kitchener is the most frequently used, and this has the boiler placed at the back of the range, and out of reach of the ordinary members of the household.

In addition to the impracticability of getting at this to clean it—a very important *dis-advantage*—there seems, in the event of a sudden and sharp frost, great danger of its bursting, if the pipes leading to and from the same to the hot-water supply should by any means become frozen.

There ought to be, and no doubt is, some simple and economical device that could be adapted to these kitcheners (without having to take out and re-set them), did but the ordinary householder know it, and it is on this ground I write, feeling sure that the insertion of this letter in the Society's *Journal* will induce some of its members to suggest a remedy, and enable every householder, so disposed, to avail himself of such suggestion, and to sleep peacefully in his bed without the fear haunting him of being suddenly blown out of it some frosty morning; and at the same time render him free from any anxiety of finding his domestics the victims of the new and, at present, imperfectly understood substitutes for the old open kitchen ranges.

F. B. W.

## NOTES ON BOOKS.

**Technical Vocabulary (English-French) for Scientists, Technical, and Industrial Students.** By D. F. J. Werhoven. (London: Librairie Hachette et Cie. 1881.)

The words and phrases given in this book are arranged under the great headings of physics and mechanics, chemistry and metallurgy, machinery and manufactures, and an index of English words affords the reader an easy key to the classification. A list of the Latin, French, English, and German names of timber trees is added.

**Reports on the Estate of Sir Andrew Chadwick, and the recent proceedings of the Chadwick Association in reference thereto,** by Edmund Chadwick and James Boardman. To which is prefixed the *Life and History of Sir Andrew Chadwick*, by John Oldfield Chadwick. (London: Simpkin, Marshall, and Co. 1881.)

Sir Andrew Chadwick died in the year 1880, at the age of 84, leaving a considerable property, the disposal of which has given rise to a large amount of litigation.

Mr. J. O. Chadwick has described fully the various incidents connected with the carrying out of the will and its numerous codicils, and has also given an account of the early history of the Chadwicks.

## GENERAL NOTES.

**Manufacturers' and Mill Owners' Mutual Aid Association.**—An Association has been incorporated by Act of Parliament, 1881, under this title, for the purpose of facilitating, as far as manufactories and mills are concerned, the objects proposed by the Act of 1876, for preventing the pollution of rivers, and also for the utilisation of waste products. The secretary (*pro. tem.*) is Mr. J. Breeze, and the office is at No. 5, The Sanctuary, Westminster, S.W.

**Canadian Fisheries.**—The supplement to the report of the Minister of Marine and Fisheries for 1880-81 contains much information relating to the value of the fisheries of Canada. The total value of the catch in the Provinces amounted to 14,500,000 dollars, in 1880 and to 13,529,250 dollars in 1879, an increase for the past year of nearly 1,000,000 dollars. The following statement shows the value of the yield of each of the principal varieties of fish:—

	Dols.		Dols.
Cod.....	4,534,000	Mackerel.....	2,178,966
Salmon .....	645,427	Herrings.....	1,511,012
Haddock .....	406,075	Lobsters.....	2,143,312
Whitefish .....	203,018	Trout .....	134,897

The codfish is obtained chiefly in Nova Scotia, where the yield reached 2,497,839 dollars, and in the Gulf of St. Lawrence, within the Province of Quebec, where it was 1,628,000 dollars. Mackerel and haddock are obtained most largely in Nova Scotia; herrings in New Brunswick; lobsters in New Brunswick, Prince Edward Island, and Nova Scotia; salmon in British Columbia; and trout and whitefish in Ontario.

**South African Diamonds.**—According to *The Colonies and India*, the gross weight of diamonds contained in packages passed through the Kimberley post-office, in 1880, was 1,440 lbs. 12 oz. avoirdupois, the estimated value being £3,367,897. These figures compare with 1,174 lbs. and £2,846,631 in 1879; 1,150 lbs. and £2,672,744 in 1878; 903 lbs. and £2,112,427 in 1877; and 773 lbs. and £1,807,532 in 1876. The annual value of the mines in the Kimberley division owned at the end of 1880 by the Government and the London and South African Exploration Co. is estimated as follows:—Kimberley, £4,000,000; Old De Beer's, £2,000,000; Du Toit's Pan, £2,000,000; Bullfontein, £1,500,000. At the end of last year 22,000 black and 1,700 white men were employed at these mines. From the Kimberley and Old De Beer's mines alone diamonds to the extent of 8,200,000 carats are annually raised, while the other two mines above named yielded 300,000 carats last year. At the diggings on the Vaal River about 250 men were at work last year. The other important mining industries of the Colony are the copper mines of Namaqualand, from which last year 15,310 tons of copper were exported, valued at £306,790. From the manganese mines in the Pearl division, 208 tons were exported; while at the coal mines in the Wodehouse and Albert divisions about 1,000 tons were raised. The salt-pans in Simon's Town, Malmesbury, Piquetberg, Fraserburg, Uitenhage, and Cradock yielded about 9,000 tons of salt. Mineral springs abound in the Colony, many of them being well resorted to, but accommodation for visitors is, as a rule, indifferent.

## THE LIBRARY.

The following works have been presented to the Library:—

An Outline History of the Hanseatic League, more particularly in its bearings upon English Commerce.

By Cornelius Walford, F.S.S. (London: Printed: private circulation, 1881.) Presented by the Author.

Plan to Liquidate the National Debt with less than the Cost of Interest. By Frederick N. Newcome. (London: Effingham Wilson.) Presented by the Author.

Ludgate-hill: Past and Present. By W. P. Treloar. (London: Griffith and Farran, 1881.) Presented by the Author.

Science for All. Vol. iv. Edited by Robert Brown, M.A., Ph.D. (London: Cassell, Petter, Galpin, and Co., 1881.) Presented by the Publishers.

Reports on the Estate of Sir Andrew Chadwick and the recent proceedings of the Chadwick Association, by Edmund Chadwick and James Boardman, to which is prefixed the Life and History of Sir Andrew Chadwick, by John Oldfield Chadwick, F.S.S. (London: Simpkin, Marshall, and Co., 1881.) Presented by the Author.

Technical Vocabulary (English-French) for Students. By Dr. F. J. Wershoven. (London: Hachette and Co., 1881.)

Birmingham Inventors and Inventions. By Richard B. Prosser. (Birmingham: "Journal" Printing Works, 1881.) Presented by the Author.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOV. 14.—Institute of Surveyors, 12, Great George-street, S.W., 8 p.m. Opening Address by the President, Mr. Edward Ryde.

Royal Geographical, University of London, Burlington-gardens, W., 8½ p.m. Opening Meeting of the Society of Chemical Industry, Burlington-house, W., 10 p.m. 1. Address by the Chairman, Prof. Abel. 2. Dr. Messel, "The Want of Uniformity in Tables of Specific Gravity."

TUESDAY, NOV. 15.—Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Discussion on Mr. Wood's paper, "Iron Permanent Way." Statistical, Somerset-house-terrace, Strand, W.C., 4 p.m. Opening Address, on the Land Question, by the President (Mr. J. Caird).

WEDNESDAY, NOV. 16.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Opening Meeting of the Session. Address by Sir Frederick J. Bramwell (Chairman of the Council).

Institute of Bankers (in the Theatre of the Lord's Institution, Finsbury-circus, E.C.), 7 p.m. Mr. Rowland Hamilton, "Money and Barter."

Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Mr. G. J. Symons, "The Gale that passed across the British Isles, October 13th and 14th, 1881." 2. Mr. J. Wallace Pegg, "The Structural Damage caused by the Gale as indicative of Wind Force." 3. Mr. C. N. Pearson, "The Meteorology of Mousserpoor, Tibet, 1880."

Geological, Burlington-house, W., 8 p.m. 1. Principal J. W. Dawson, "Notes on *Protolites* and *Facities* from the Denbighshire Grits of Corwen, North Wales." Dr. Henry Hicks, "Additional Notes on the Last Plants from the Pen-y-glog Slate-quarry, near Corwen, North Wales." 2. Mr. E. E. Berry, "Analysis of the Rocks from the Charnwood-Forest District." (Continued, with Notes, by Prof. T. G. Bonney.)

Archæological Association, 32, Sackville-street, W., 8 p.m. Opening Meeting of Session. 1. Prof. Haylor Lewis, "The Boorg or Biffr, Cairo." 2. Mr. Gordon M. Ellis, "The Measurements of Ptolemy in Relation to the Western Portion of Britain."

THURSDAY, NOV. 17.—Royal, Burlington-house, W., 4.30 p.m. Linnean, Burlington-house, W., 8 p.m. Sir John Lubbock, "The Sense of Colour among some of the Lower Animals." 2. Mr. C. B. Clarke, "A Hampshire Oak not Figured in English Botany." 3. Prof. T. S. Cobb, "New Entozoon from the Ostrich." 4. Mr. B. I. Lynch, "A Confrance for Cross Fertilisation in *Eschsch. perfoliata*." 5. Sir John Lubbock, "Observations on Ants, Bees, and Wasps." Part IX.

Chemical, Burlington-house, W., 8 p.m. 1. Dr. G. Stone and Mr. Tribe, "Aluminum Alcohols: Their Products of Decomposition by Heat." 2. Mr. W. G. "The Chemical Action of Decomposing Vegetable Matter on the High Fuming Sulphuric of the Carboniferous Period."

## CONTRIBUTIONS TO THE READING-ROOM.

The Council beg leave to acknowledge, with thanks to the Proprietors, the regular receipt of the following Transactions of Societies and Periodicals during the year:—

## INDEX TO VOL. XXIX.

## A.

f. F.A., C.B., F.R.S., *chair*, increase of deaths from explosions, *air*, recent progress in the manufacture of steel, 597.  
spt., F.R.S., presentation of medal

allance, 613

Prof. W. G., F.R.S., *Cantor* scientific principles involved in electing, 730, 739, 749, 759; syllabus,

languages of, *paper*, R. N. Cust, 296  
uth, industrial resources of, *paper*,  
the Frere, Bart., G.C.B., 185, 202  
—, diamond fields of, *paper*,  
Murray, 370

—, diamonds of, 372  
section—see "Foreign and Colonial

returns for 1881, 766

re in Travancore, 763

—, in Victoria, 768

pressed, locomotive for tramways,  
s, &c., *paper*, Col. Beaumont, 384  
ntess of, *chair*, domestic economy  
s, 637

t., *disc.*, British rule in India, 351

oyal, hall, 367, 509

edal, list of awards, 319; award

Hofmann, F.R.S., 625, 640

fr., *disc.*, domestic economy con-

39

ir Rutherford, K.C.B., *chair*, Bri-

ma, 590

horticulture in, 925

marble quarries of, 450

iss, *paper*, domestic economy con-

40

, A., *disc.*, a new mechanical fur-

32

science and mechanism, notes on,

t, 727, 733

engine, 554

's college, Glasgow, 836

, Miss, *paper*, domestic economy

s, 638

ntelligence, *juvenile lectures* on, by

Comanes, F.R.S., 85, 105

y deposits in Sonora, 845

m., obituary, 317

colours, annual report, 652

kmanship, regulations respecting

for, 63

active silks of, 99

d, province of, and its inhabitants,

, Q.C., *chair*, trade marks, 493

, Trans-Australian Railway, 94

—, vegetation of the Australian

621

n fruit for England, 778, 798

— colonies, 778

population of, 768

Prof. F.R.S., *disc.*, future develop-

of electrical appliances, 499; *disc.*,

railways and transmission of

by electricity, 573

## B.

Col. H. P. *letter*, signalling by

of sound, 145

Dr. *disc.*, industrial resources of

Africa, 227

s, sponge trade in the, 102

active, 613

Bamber, Mr., *disc.*, London fogs, 59

Barber, Mr., *disc.*, domestic economy con-

gress, 685

Barff, Mr., Society of Arts' patent bill,

813

Barkly, Sir H., K.C.B., F.R.S., *chair*, lan-

guages of Africa, 298

Barlow, F., *disc.*, British Burma, 585

Barnett, Miss, *disc.*, domestic economy con-

gress, 640; *paper*, 641

Barry's "Victors of Olympia," 19; in-

fluence of Barry upon English art, *paper*,

by J. Comyns Carr, 20

Bartley, G.C.T., *disc.*, domestic economy

congress, 684

Bayley, Miss Clive, *paper*, domestic economy

congress, 641

Beaumont, Col., *paper*, Beaumont

compressed air locomotive for tramways, rail-

ways, &c., 884

Becker, Miss, *disc.*, domestic economy con-

gress, 639

Bell, A. Graham, *paper*, the photophone,

38; diagrams, 60

Bengal, cinchona cultivation in, 844

Bevan, J. O., *letter*, prevention of floods, 287

Bidder, Mrs., *chair*, domestic economy con-

gress, 638

Birch, R. W. P., *disc.*, river conservancy,

292; *letter*, 317

Bird, P. Hinckes, *letter*, house drainage

tests, 64

Blackley, Rev. W. L. *paper*, domestic

economy congress, 684

Blake, Dr. Carter, *disc.*, modern gold min-

ing, 164

Blast furnace cinder, 509

Bodmer, Mr. *disc.*, Beaumont

compressed air locomotion, 392

Bohemia, fruit gardens of, 555

Boiler explosions, new theory concerning,

727; *letter*, J. W. Wood, 737

—, kitchen, *letter*, L. E. Fletcher, 198

Bologna, public instruction in, 747

Books, NOTES ON:—

Association internationale pour l'eau

potable, 146

Ball, V., diamonds, coal, and gold of

India, 710

Bourne, S., trade, population, and food,

198

Burgess, J. W., treatise on coachbuilding,

710

Chadwick, Sir Andrew, Reports on the

estate of, 873

Christy, T., new commercial plants, 614

Clements, H., fields of Great Britain, 419

Designs and catalogue of furniture, &c.,

147

Fawkes, F.A., horticultural buildings, 419

Haslusk, Pres., lathe work, 846

Hasting, C. W., water-works' statistics,

614

—, gas-work statistics, 614

—, gas and water companies' directory, 614

Legendary history of the Maoris, 634

Leighton, J., suggestions in design, 710

Liveridge, A., report on museum for

technology, &c., 198

Melbourne international exhibition cata-

logue, 645

Mitchinson, A. W., expiring continent, 366

Notes of observation on injurious insects,

454

Parry, J., water, its composition, collec-

tion and distribution, 368

Richardson, J., smaller manual of modern

geography, 199

Robertson, W. R., agricultural class-

books, 472

Studies in water colours, 710

Urquhart, J. W., electro-typing, 366

Wardle, F., wild silks of India, 366

Wershoven, D. F. J., technical vocabulary,

871

Botly, W., vote of thanks for chairman's

address, 15; *disc.*, sanitary protection

association, 125; *disc.*, forest conservancy

in India, 159; *disc.*, participation of labour

in profits, 291; *disc.*, discrimination and

artistic use of precious stones, 447; *disc.*,

buying and selling, 532; *disc.*, trade rela-

tions between the colonies and the mother

country, 545; *disc.*, British Burma, 584

Bourne, Stephen, *paper*, trade prospects,

186; *disc.*, trade relations of the colonies

and the mother country, 544

Bourne flow (Croydon), 84

Boyle, L., *disc.*, Canada, 484

Brady, Sir Antonio, vote of thanks for

chairman's address, 15; Society of Arts' patent bill, 812

Bramwell, Sir F. J., F.R.S., opening address

of 127th session, 6; *chair*, the photophone,

37; *chair*, lighthouse characteristics, 306;

*disc.*, increasing number of deaths from

explosions, 418; *chair*, electric railways,

and transmission of power by electricity,

567; *chair*, annual general meeting, 645;

Society of Arts' patent bill, 809; some of

the developments of mechanical engi-

neering during the last half-century, 868;

re-elected chairman of council, 678

Brandram, Mr. *disc.*, languages of Africa,

306

Brant, Miss E. M., *paper*, domestic economy

congress, 638

Bread reform, *letter*, Dr. Gilbert, F.R.S.,

144; Dr. Graham on, 448; Miss M.

Yates, 553

Bridgewater, Mr. *disc.*, trade relations of

the colonies and the mother country, 545

Bright, Mr. *disc.*, electric railways, 560

Bright, Sir C., *disc.*, recent advances in

electric lighting, 436

British Museum, printed catalogue of books,

504

Brussels international industrial congress,

29; *letter*, P. Splingard, 93

Buchan, W. P., *letter*, house-drainage tests,

84

Buchanan, J. Y., *paper*, deep-sea investi-

gation, and the apparatus employed in

it, 330

Buckland, Frank, obituary, 94

Buckton, Mrs., *lecture*, domestic economy

congress, 673

Building arts of India, *paper*, General

MacLagan, 516

Buoys, gas-lighted, 419

Burma, British, *paper*, Sir Arthur Phayre,

G.O.M.G., 590

Burton, Capt. R.F., report on two expe-

ditions to Midian, 98

Buying and selling, its nature and its tools,

*paper*, Prof. Bonamy Price, 526

## C.

Caithness, Earl of, obituary, 455

Calder, Miss Fanny, *disc.*, domestic economy

congress, 638

Campbell, C., *disc.*, tenure and cultivation

of land in India, 436

Campbell, Sir G., K.C.S.I., *paper*, tenure

and cultivation of land in India, 436

influence upon various industries," by R. Brudenell Carter, F.R.C.S., 817, 827, 837; syllabus, 508
